The fact that the book has reached its tenth edition is more than sufficient evidence of its utility and popularity. The letter-press is clear, the language explicit and the illustrations so well executed, that the student scarce needs a cadaver to work on when studying his anatomy. The volume includes a copious bibliography of most recent writers and references and leaves nothing unsaid to be desired by either the student or the teacher in the phraseology, appellation and distribution of the various nerve ganglions and plexuses. To say the least we cannot say too much of the value or the scope of the book.

MEDICAL ELECTRICITY. A practical handbook for students and practitioners. By H. LEWIS JONES, M.A., M.D., F.R.C.P., Medical Officer in charge of the Electrical Department in St. Bartholomew's Hospital. (H. K. LEWIS,

186, Gower Street, London, W.C). 8vo., pp. 474, price, 10/6.

The difficulty of managing and fitting up the necessary apparatus as also the scanty technique of practical manipulation being so little taught in medical institutions have made Medical Electricity occupy a much more humble position in therapeutics than it deserves. In the book before us these objections are obviated; as the author has been at great pains to clearly define both theory and practice and simplify matters by means of precise illustrations and intelligible language.

He complains, and justly so, that while fickle France has become constant by maintaining two monthly journals, dealing exclusively with the influence of electricity on the animal frame in disease and the over beset Yank actually supports an energetic Electro-therapeutical Association, England alone is dumb and practically condemns to oblivion or shuts her eyes to what she should put on the highest rung of the ladder of therapeutics.

He treats his subject with a master hand and beginning with the history of electricity splits the work up into fourteen chapters, guiding us carefully through the intricacies of the maze of construction and working of the various apparatus, till he gradually brings us to the human frame of which he explains the physiology and shows the how and wherefore of therapeutic application in common ailments as well as nervous affections such as hysteria, cerebral disease, epilepsy, paralysis &c. Step by step he carries us to the surgical amphitheatre with its huge array of lancets, knives and deadly instruments and, showing how useless the most of these are alongside of the galvanocautery and electrical re-sorption and removal of abnormal growths, he takes us to the death-chamber where he assures us that in the absence of other testimony or even in corroboration or contradiction of such oral or written evidence tendered it is quite possible for the battery to enable the Autopsy-Surgeon to specify correctly the exact time at which death had occurred and gives us convincing proofs that when all other means had failed to detect suspended animation in cases of apparent death electricity had stepped in and prevented the victim from being buried alive.

Direct application of electricity to many of the animal and vegetable poisons decomposes and renders them inert; but, although it is still an open question as to whether these same reactions will take place when these substances are injected into or absorbed by living tissues, Dr. Jones declares that electrolysis acts wonderfully on the mineral poisons and quotes authentic instances of arsenic and lead poisoning where the patients' lives have been saved, and the whole of the poisonous metals abstracted from their tissues, by subjecting them to the electric bath.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

The undermentioned candidate has passed the M.D. Exam. — Hemchandra Sen, Hosp. Asst. Bepin Bihari Bose, Mirza Muhammad Sajid, Muhammad Jwa, and Raja Darsi Stain were apptd. third class Hosp. Assts. from 27th March to 9th, 13th and 14th July, 1895, respectively.

Third grade Hosp. Asst. Rishan Lal assumed charge at the Contagious Diseases Hosp. Rangoon, on 31st July 1895.

The following 3rd grade Hosp. Assts. assumed charge at the hospitals on the dates opposite their names:—

Thana Ram, Jail Hosp., Mandalay, 24th July 1895.

Abdus Shakoor, Civil Hosp., Ma-u-bin, 31st July 1895.

Sunder Singh, Civil Dispy., Katha, 31st July 1895.

Third grade Hosp. Asst. Sunder Singh assumed additional charge of the Jail Hosp., Katha, on the 31st July 1895.

Third grade Hosp. Asst. Manag Kyaw Lay assumed charge of the Genl. Hospl., Mandalay, on 29th July 1895.

Third grade Hosp. Asst. Shaik Husein assumed charge of the Railway Hospl. Mohnyin, Katha, on 31st July 1895.

The following 3rd grade Hosp. Assts. posted temporarily to the stations noted against their names:—

M. Rajagopaul Moodelliar, Mandalay.

H. Doraswami Pantulu, Tharrawaddy.

P. Govinda Pillai, Pynmana.

J. H. Yeaslian, Minbu.

T. A. Ramaswami Aiyar, Pakokku.

G. O. C. C.

Surgn.-Capt. H. B. Luard, of 22nd Punjab Inf., takes med. charge of the 45 Sikhs, vice Surgn.-Capt. G. H. Frost.

ASSAM GOVERNMENT.

Privilege leave for 24 months is granted to 3rd grade Hosp. Asst. Prasanna Kumar Purkayastha, Nishargard-Mantpur Road Circle, from 1st August 1895.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

MULBONEY—July 21st, at Southwood, Simla, the wife of Surgn.-Maj. T. R. Mulroney, I. M. S., of a daughter.

BAIRD—Aug. 7th, at Musoorie, the wife of Surgn.-Maj. A. Baird, A. M. S., of a son.

HART—Aug. 10th, at Calcutta, the wife of J. Bush Hart, M. B. C. V. S. L., of a son.

BRANDON—Aug. 12th, at Ootacamund, Madras, the wife of Dr. Brandon, Chaplain, of a daughter.

DURRELL-PANK—On the 18th August, at Ajmere, Rajpootna, the wife of Surgn.-Maj. P. Durrell-Pank, of a son.

MARRIAGE.

SEXTON—CONWAY—July 31st, at the Roman Catholic Church, Chakrata, Michael John Sexton, Surgn.-Capt. M. D., A. M. S., to Catherine (Katie), eldest daughter of Captain John Conway, the Duke of Cornwall's Light Infantry.

DEATH.

WHITE—Aug. 2nd, Madras, Willie A. F. White, only son of the late Asst. Surgn. C. W. White, M. D., aged 35 years.

NOTICES TO CORRESPONDENTS.

An Enquirer (Delhi) seeks for information as to the method of examining blood for parasites. We feel sure Dr. Patrick Kehir, F. R. S., will oblige with an article on this subject.

S. K. M. (Bilam).—Try your patient, *give* 10-grain doses of salicylate of soda *t. d.* after meals, and give him 5 grains of quinine at midday and midnight. Diet to be milk and vegetables.

E. J. W. (Sivillipatur).—Your paper to hand. Many thanks. It will receive early attention.

E. S. (Agar).—We think it will be more advantageous if you and your colleagues, who are anxious to join a provision, will send us a letter signed conjointly in the terms of Comment on this subject on page 183 of this issue.

D. W. R. (Yamathu).—Your interesting article has been received.

M. E. D. (Malacca).—We have received your paper.

J. A. De O.—There is a popularly but not properly, so, termed preparation of "Valerianate of Ether." This may be made in one of three ways (a). Dissolving $C_{10}H_{18}$ or essence of Valerian in rectified ether (b) Treating $C_{10}H_{18}O$, HO , (or valerianic acid) with freshly distilled rectified ether (c) Letting a mixture of 4 parts by weight of 80° Alcohol and 2 of 0.728 Ether percolate slowly through 1 part by weight of powdered Valerian Root. But be it remembered that the majority of commercial Valerianates are prepared not as they should be from Valerian but synthetically from Fousel oil, or amylic alcohol.

J. R. D. (Sultanpur). If you have just grounds for your belief and can thoroughly substantiate your statements it is your duty to inform the police. Always keep in view, however, the fact that as a physician the confidence of your patient has to be respected.

T. A. (Gadag). We hope your paper will appear in our next number.

F. S. M. (Mysore).—Your paper to hand and will receive early attention.

Hospital Assistants Madras.—Complain that the grant of free quarters has not yet been made them and they feel this a serious hardship to which we kindly invite the attention of the Madras medical authorities.

H. P. B.—Many thanks for your paper.

Our Readers.—On page 173 of this issue appears a leader "Value of Medical Combination." We mean Value, not value, as some may think; for to our mind a medical combination is to the Profession what the *Valves* of the heart are to the circulation of the life stream.

ACKNOWLEDGMENTS.

We acknowledge receipt of the following with thanks:

Risley Esq., Secretary to the Government of Bengal; W. C. Mudge, Esq., Calcutta; M. Verghese, Cannanore and others.

PHENOCOLL IN PREGNANT WOMEN.

After trying this drug for some time in the above condition TITONE finds that though of *inferior* value in malaria, it exerts next to no action, (even in 5-grain doses every 2 hours), whatever on the pregnant uterus. He therefore contends that in phenocoll is found a malarial drug as powerful as quinine *without* the *unfavourable* influence of the latter on pregnancy.

A CASE OF SPONTANEOUS RUPTURE OF THE HEART.

(Szegede). The body of a 67-years old woman, suddenly deceased, was brought to police examination. On the posterior wall of the left side of the heart, at a thinned spot, was a fissure 8 m.m. long, through which about 800 gm. of blood had poured into the pericardium. The immediate cause of death was this rupture. The heart muscle was fatty degenerated, and an endarteritis deformans was present, while both kidneys were shrunken.—*Good Health.*

COURT FEES.

The fees allowed in Great Britain for a medical witness for attending to give evidence in a criminal case are 1 guinea per diem and travelling expenses. No special allowance is made for examinations except in exceptional cases. If no order for payment has been made by the court nothing will probably be allowed.

HEALTH LEGISLATION AND THE NEEDS OF INDIA.

By LEWIS HART, D.M.S.

Editor, British Medical Journal.

THIS is probably the most representative and influential meeting of medical officers of health that has ever assembled in Great Britain. I appreciate the high honor of presiding over it. Two things add to its importance: first, that it meets not as an isolated or powerless body, but as an integral part of that British Medical Association which includes practically nearly the whole of the authorized members of the medical profession in these kingdoms, and certainly all its most authoritative and highly-informed members, both in this country and throughout the British dominions and possessions; and, secondly, that this meeting it will have the power of sending up its final recommendations and decisions to the central executive Council and to the Parliamentary Bills Committee of that Association, and through its machinery of transforming them in due time into the basis of legislative action by bringing them within the sphere of the Government departments, and, if necessary, of securing legislative action. What we do and say here, therefore, will, according to its intrinsic merit, be likely permanently to affect public opinion, and ultimately the municipal and legislative proceedings of the Empire.

The Healthiest City in the World.—Let me offer you welcome and congratulation at meeting here in the metropolis of the world at once the greatest and the most healthy of cities. Since last the British Medical Association met here, progress has been made in the science and practice of public health administration and the prevention of disease which has amounted almost to a revolution. There was then no section of public medicine such as that over which I have now the honor to preside, and the public health service throughout the country was almost in its infancy. The results of the good work done and its great effects on the health and happiness, and therefore on the material prosperity of this great community, as of the country at large, are sufficiently shewn in the bare fact that the mortality of this city has fallen from 22 per 1,000 to 18; whereas but for improved sanitation, due to the advancing knowledge of the methods and principles of preserving the public health, achieved and demonstrated by the medical profession, it would have risen inevitably in proportion to the increasing density of population to at least 24 per 1,000. The science, art, and practice of public health administration are, I am proud to say, almost wholly British; the other nations of the world have, some with vigour and activity, and others slowly but imperfectly, accepted our demonstrations and followed our practice, but for the most part all of them still lag in the rear of British sanitary legislation and administrative practice. In that great advance I am happy to be able to affirm, and we may all take pride and credit in our progress from the fact that a main part

has been played by the British Medical Association, and its members.

The Completion of the Sanitary Law.—The last great conception of the sanitary reform of England was due to our much-lamented Associate, Ramsay, of Cheltenham, a general practitioner of the highest order of administrative genius, who laid down principles and methods, which were partly, but by no means perfectly, brought into play by the Public Health Act of 1875. To him and to a small active band of far-seeing workers, prominent amongst whom were Sir HENRY AINSLIE, Dr. WILLIAM FARR, and Mr. W. H. MONAGHAN, J.L., and with whom I had the honor of being an active co-worker, was wholly due that great report of the Royal Sanitary Commission which laid down the principles and methods of the legislation which has proved so beneficial and life-saving to the millions of this country. It is true, as it is true, that by the efforts of that legislation every man in this country enjoys two and a-half years more of active healthy life than he could have anticipated thirty years ago, and every woman three and a-half years; the debt of gratitude for this great boon is mainly due to the men whose names I have mentioned. Alas! only AINSLIE and myself survive out of this devoted band, to watch and to rejoice over the results achieved and the progress still in course. RAMSAY, FARR, MICHAEL, STUART have gone over to the majority, undistinguished and unknown by their country, and without any of those marks of distinction from the crown which would undoubtedly have fallen to their lot had the destruction of life in lieu of the saving of life been their occupation. Yet I venture to hope that some day their names may be distinguished in the roll of honor—comparatively barren although each posthumous honor may be—and at any rate in our memory and in the records of the profession they will always hold a high place among the benefactors of mankind, among the great worthies of our age. For theirs was good and great work, nobly and well done, for the pure love of mankind, in utter disinterestedness and often to their great loss. Perhaps I alone, who worked day by day alongside of them, can tell how incessant was their labour, how little it was known or regarded, how frequent their baffling disappointments, and how readily they gave way to the statesmen and legislators who finally took up their work and assumed its public sponsorship.

The Blunders of Mr. Stansfeld.—The Public Health Acts, to which were attached the names of Mr. STANSFELD, of MR. SLATER-BOOTN, of Mr. DAWSON, and Mr. CLAYTON HARDY, are very largely only the public formulae of the aims and outcome of our work. It is only true to say that as far as our ideals and perfected schemes were depicted from health legislation and our present sanitary system have been named and are rendered imperfect. To mention only one instance, our system, carefully drawn in all its details, included the creation of large sanitary areas, whose boundaries should be established with a due regard to the watershed, the creation of boards of sanitary districts, the existing sanitary councils for local sanitary administration, and the appointment of these areas of medical officers of health over, amongst others, to have the sole duty of sanitation, safely and free from the temptations and distractions of general medical practice.

and having fully recognised Mr. STANSFELD in his bill recognised three principles, but acted upon them only in a partial and incomplete manner, actuated by the doctrinaire spirit which has so largely interfered with his usefulness as a statesman throughout his career. He insisted on making these arrangements depend upon the intelligence, the generosity, and the far-seeing spirit of an infinite number of small local bodies. It was in vain that as Chairman of the Parliamentary Bills Committee of our Association I urged upon him with incessant and obstinate energy the necessity of making these broad general principles compulsory instead of voluntary. To all remonstrances he answered that "you must trust the people," that his "bill was intended to be educational and not coercive," and "the authorities must learn by their errors as well as by their achievements." "Besides," he pointed out, "you must read between the lines of my Bill. I am offering them all a bribe to do the right thing, and this they will readily accept. We offer to pay one-half of the salaries of the medical officers." I am sorry to say that he was quite obdurate under the sharpness of my remonstrances, and I fear finally the somewhat contemptuous tones in which they were sometimes couched led to a personal coolness which subsequent differences of opinion did not mend.

Mr. Ritchie's County Council Bill.—Mr. RITCHIE'S County Councils Bill did something to repair the blunders of Mr. STANSFELD, but omitted to appoint medical officers to make the work of the county councils effective. We had recourse to the good offices of Mr. STANSFELD to introduce provision for county medical officers which we understood that the Government would be quite willing to accept; but here again Mr. STANSFELD'S doctrinaire views intervened, and I was unable to induce him to word the amending clause so as to make such appointments compulsory. Thus this Bill also was marred in its usefulness. Only a few of the English county councils have appointed medical officers to assist them in their duties, and notwithstanding the conspicuous usefulness of the work of such men as Mr. SHIRLEY MURPHY, Dr. REID, Dr. WHITEKORN, and their colleagues, those most important appointments have only been made in a few cases. Happily I was more successful in dealing with the County Councils Act of Scotland. There, with the help of Dr. FARQUHARSON, Sir CHARLES CAMERON, and co-operating with the Scottish Medical Officers Association, we were able to obtain a compulsory clause and every county in Scotland now has a county medical officer. It is universally recognised that this arrangement is conferring untold benefits upon the sister kingdom. In many other respects, and especially in relation to a combination of sanitary districts, the provision of adequate paid and skilled medical officers over adequate areas, much still remains to be done to complete and carry out the health arrangements of this country as we originally devised them.

The Relation of Health to Water Supply.—The few further words which I have the duty to address to you as utterances from this chair must necessarily be limited to one or two selected subjects from the wide range over which our programme will extend. You will not be surprised if I deal especially with the subject which has

so largely occupied my attention during the last year, namely, that of the relation of poisonous disease to our water supplies; and if, coming as I do from a study of the health conditions of India, I lay some stress upon the sanitary needs of that great empire, and upon the means of dealing with the most pressing of these requirements. It is now exactly thirty years since I succeeded in demonstrating, to the satisfaction of all authorised sanitarians, that the cause of the great epidemic of cholera of 1865 in the East End of London was the temporary breaking down of a single pump in the works of the East London Water Company and the temporary disuse of one filter bed. This breakdown led to the distribution throughout the East End of London of water from the river Lee, which had been for a few days polluted by the discharge from the sewers of the house of a family suffering from relapsing cholera, brought from Egypt to this country. That one strange concurrence of river pollution and inadequate filtering, produced within a few weeks and within a limited area 1,000 deaths. It cost no small trouble to prove indubitably the striking series of facts which were necessary to establish this conclusion on an unassailable basis of evidence. From that time forward, however, I have spared no pains or expenditure necessary to track the various epidemics of cholera throughout the world due to sewage-tainted water.

Cholera a Purely Waterborne Disease.—Thus in 1869 I traced the cholera epidemics of Toulon and Marseilles to the pestilential state of the water-supply, a cause which was not then widely accepted, but has now been so, so that Dr. BROUARDEL, one of our most distinguished converts, has acknowledged that the outbreak of cholera in Marseilles in October 1892 was principally due to contamination of the drinking water by sewage. The same cause is now acknowledged by M. MONON, by Dr. SHAKESPEARE, and by Dr. PROUST to have been operative in the widespread epidemics in Finistère in 1885 and 1886. The sudden outbreak of cholera in Paris in 1892 was undoubtedly due to the consumption of Seine water. Happily the French have now recognised this lesson, and Paris has a water supply which is mainly independent of the Seine, so that no future cholera epidemic is likely to occur there. I have already written the history of the great cholera outbreak at Naples in 1884, and at Genoa in the same year. By a telegram to BRANTINI warning him to investigate the pollution of the water supplied by the Niccolay aqueduct I was able summarily to stop that epidemic.

In the excellent description of the Spanish outbreaks of cholera in 1865 by Mr. GEORGE HIGGINS, the dependence of cholera outbreaks and of the enormous localities attending them in that year upon sewage-tainted water was most conclusively proved. The outbreaks in Russia in 1892, and of the cholera in Hamburg in the same year owed no other cause, and KORT has fully recognised this, so that the improved water supply that Hamburg now enjoys may be counted upon as preventing 2 future cholera outbreaks. I ventured to predict during 1898 that, however often cholera should be imported to this country, it would never become epidemic owing to the improvements in our water supply, but that cholera

of the water supply, and the water supply in towns, ports, and rural districts, and the water supply might be improved, and what the water supply is known or inadequately protected. This doctrine was opposed to the latter. I by no means claim the exclusive credit of having preached and proved the doctrine that cholera is a waterborne disease, due to the poisoning of our water supplies with sewage: that doctrine was first laid down by SNOW, of whom I was the constant apostle. It was illustrated by SIMON with all his wealth of quaint eloquence, but even until a late date it was doubted and denied by some of the most eminent authorities, and the official utterances of the College of Physicians at no distant date were to the effect that it was not probable that in the case of cholera the influence of water would ever be shewn to consist in its serving as a vehicle for the poison generated in the bodies of those who had suffered from the disease. So late as 1866, immediately prior to my assuming the editorship of the *British Medical Journal*, that journal declared that "we do not believe a single case on record either proves or justifies the fact that a man's stomach, then and there produced cholera in him." The theory that cholera is wholly, essentially, and universally a waterborne disease is wholly mine; and if it is, as I believe it to be, now universally accepted, I venture to say that this acceptance is due to the laborious persistence with which I have accumulated the proofs of it from every part of the world, and have repeated them in my addresses to the profession on this subject, in America, in India, as well as in this country. That doctrine is now becoming common place in Europe at least; although, as I shall presently have to state, it is still ignorantly resisted in India, to the great peril and sacrifice of hundreds of thousands of lives of our fellow-subjects. But even in England our water supplies are still in too many places scandalously and dangerously tainted, and the result is shewn in that prevalence of typhoid which is, as I contend, not less surely and inevitably traceable to a polluted water supply than is cholera itself. All that has been done and is being done to ward off cholera is in like measure operative in my view of the facts to prevent typhoid.

Waterborne Typhoid.—In the reports on waterborne typhoid which I am now publishing in the *British Medical Journal*, I have investigated the data in respect to 206 distinct outbreaks of typhoid fever in this country from 1871 to 1890, and from these reports it will be seen that they are all of them due to neglects of the water supply. In that period upwards of a hundred millions have been spent in improving our water supplies, and with the result: that whereas the mean annual death-rate per million living from those two diseases was, as stated by Dr. THOMAS THORNE, 567 in the five years 1869—73, it was only 179 in the five years 1888, 92, so that during the year 1892 alone no fewer than 14,282 persons escaped death from such fever who would have died if they had been living under the regime of 1869. Only a million lives have been saved during the period in question by the improvement mainly of our water supplies. To take a few examples only: At Manchester, from the annual death-rate from enteric fever of 1,214 per 10,000 prior to the improvement of

its water supply, fell afterwards to 83. At Chelsea the fall from the same cause was from 15 to 84, at City from 104 to 14, at Fenchurch from 10 to 4, and at Finsbury from 14 to 4. To show an enormous extent, I still provide my report, to which I venture to refer you, gives abundant and astounding evidence, and it is still further emphasised by the continued prevalence of typhoid fever in this country, which, however diminished, is still diabolical and discreditable to our sanitary authorities. London itself is continually in danger, and will remain so, so long as we continue to draw our water supplies from the Thames, which is subject to enormous and dangerous, though variable, pollution with sewage. No sewage-tainted water can ever be employed with safety for the supply of any community, great or small, although of course the variability of the extent and the specific character of the pollution lead, together with seasonal influences and changes of temperature, to fluctuation in the number of typhoid poisonings which the water effects. Every case of typhoid, is in fact, a violent death, an example of water poisoning, and should be the subject of sanitary inquest.

Indian Sanitary Needs.—If we turn to India, that great empire in respect to which we have such immense Imperial responsibilities, the case is still stronger, and naturally the needs are far greater. Unhappily there has been and there is still the most ignorant and monstrous opposition to the diffusion of our modern knowledge on this matter, to its application to Indian sanitation. A stolid resistance—to use the appropriate words of Mr. MACNAMARA—of the water theory of cholera was long offered by those in authority. Surgeon-General CONNINGHAM, Sanitary Commissioner to the Government of India, in his report for 1872, said: "That it would be a gross exaggeration, as it would be pure assumption, to affirm that the troops and other communities who were attacked suffered because they drank water which had been contaminated with cholera discharges." And again: "The belief in the dissemination of cholera through water is founded on bare assertions altogether unsubstantiated by details—bare assertions such as would not be received by any judicial court, even in the pettiest case that could be brought before it." Unhappily outworn views of this obstinate and tyrannical "Sanitary Commissioner" who enjoyed a long lease of official power have swayed official opinion.

Stolid Resistance and Antiquated Prepossessions.—Unhappily “stolid resistance” and antiquated prepossessions such as this far are more seriously important in India than they are or ever could be here; for under the system of medical organisation which exists in India, one man in high place, such as Surgeon-General CUNNINGHAM, may dominate and intimidate the whole system. Indian sanitation is not a scientific but an official system. There does not exist there any independent medical opinion. All are in the employ and under the thumb of a official authority. The oldest man in the service are the highest in official position. Their ignorance is often the standard by which their juniors are judged, their prejudices become a despotism, and their follies a tyranny. It

was for a long series of years as much as a man's promotion was worth to dare to avow the opinion that cholera was a waterborne disease, and that it was carried from place to place along the lines of human communication. The idea that it was spread and diffused by great concourses of people becoming infected by the sewage-tainted water of religious festivals was treated as not only a folly, but an offence. The two things may be concurrent, said an eminent official wiseacre, but it is a wild absurdity to treat them as cause and effect. Unhappily this gentleman still holds high office at an advanced age.

A Disgraceful Public Document.—And so it is that until lately Indian medical officers who dared to accept the patent facts and to aver that particular outbreaks of cholera, of typhoid fever, and of dysentery, were due to contamination of the drinking water, were subject to persecution. Medical officers of all grades were expected to show respect to their seniors by invoking, as the efficient causes of cholera outbreak, telluric influences, pandemic waves, epidemic constitution, cholera mists, blue clouds, cholera blasts, the influence of trees and such like bogies. Nor is this influence yet extinct. Shameful to say, the Army Medical Regulations for the management of cholera are still produced and reprinted under the same death-dealing and ignorant superstition. All the most patent facts of our knowledge concerning cholera are still ignored, and in that scandalous public document, which is still supposed to be the handbook of our medical officers, cholera is treated as a contagious and mysterious disease, of which the origin is unknown, of which the very advent is to be the signal for panic and scare. On the appearance of cholera the hospital or the barrack is to be evacuated, troops are to be marched away to a distant cantonment, at right angles to the wind, they are to be collected together and amused by games and entertainments, daily reports are to be telegraphed hither and thither to distant high officials, while the most obvious precautions as to boiling the water, quarantining and examining the native servants, the cooks, and the food supplies, are omitted altogether or only cursorily alluded to. I cannot weary your patience by criticising in detail this most disgraceful document, but I may in passing appeal to the heads of the Indian Medical Service and of the Army Medical Service here to withdraw so discreditable a document, and one so dangerous, not only by its direct teaching but by its indirect influence.

Appalling and Ill-digested Reports.—I am ashamed to say that until my recent visit to India I was so repelled by the appalling mass and ill-digested and uninformative arrangement of the sanitary reports of the Commissioner to the Government of India and of the Indian and British Army Medical Service, that I could never even bring myself to read them, and I doubt whether any one in this country has read them, with any care or attention. Their arrangement alone is a very height of absurdity. They are so artificially divided, and so ill arranged, that it is almost impossible to trace the sanitary history of any body of troops or of any regiment, and when one comes to read the comments and reports upon them of the sanitary officers of provinces, or of army

medical officers, one can read in every line intense discouragement, a mere weary compliance with the duty of filling in innumerable foolish returns, and a disgust with a system which has apparently been dictated in the pure spirit of what may be called book-keeping, and without any knowledge or regard to the needs of sanitary science and practice. The last vast and bulky Blue Book issued by Surgeon-General RICE, who has just vacated the office of Sanitary Commissioner to the Governor-General of India, is a good example of the costliness, the futility and the impotence of the present system. I defy anyone to extract from it any useful information as to the origin, diffusion, and means of extinction of any single epidemic of cholera or typhoid during the year in India. There is no mention of filtration of water or of boiling of water, or of the examination of food supplies, or of anything which one wants to know. There is an utter absence of the scientific spirit, and a still more complete absence of any practical proceedings. I was only, when in India, able to find evidence of the adequate investigation, and of adequate means of extinction, of any single cholera or typhoid outbreak amongst the troops in three reports, and they were all the reports of one man—Professor HANKIN, of Agra. In each case they distinctly shewed the outbreak of typhoid or of cholera, at Lucknow, Cawnpore, and Agra respectively, to be due to infected water, to milk poisoned by infected water, or to infected food supplies, and they pointed conclusively to the simple and easy means of extinction. One looks in vain in the vast Blue Book of Dr. RICE for any such intelligent appreciation of the causation of cholera and of typhoid, and in his comments that highly placed and distinguished officer passes over the work of the investigation of Professor HANKIN with a cursory, depreciating, and misleading allusion to it. There is in the whole of India, with the single exception of Professor HANKIN's laboratory at Agra and of the municipal laboratory of Dr. SIMPSON* at Calcutta, no provision for that bacteriological study which is now the first element in sanitary efficiency. In the whole of the Bombay, Madras and Burmah presidencies there is no skilled water examiner and no bacteriological laboratory. This seems incredible, but it is literally true.

The Discouragement of Sanitary Studies by the Government of India.—Medical officers are not even allowed microscopes, and if when they supply them at their own cost they apply for the necessary and inexpensive stains and other minor apparatus necessary for their efficient use, they are told that these are no part of a medical officer's equipment or duty. The sanitary commissioners and assistant commissioners of India are for the most part army medical officers who have had no special training, who are liable to frequent removal and diversion to other duties, and the sanitary officers of great districts are habitually overloaded with an immense category of duties which would make it impossible for them to fulfil their duties of health officers even if they were unguilted from

* Designed and fitted up by the municipal analyst, Dr. August G. Chav, with the assistance of Mr. J. D. Jones in 1900-1.—J. M. A.

† Can this be true? How about the office of the Chemical Engineer of these presidencies?—J. M. A.

made in the whole system and of the administration, the great sanitary needs of India will never be met. You will pardon me for occupying you with a subject which may seem to be in part foreign to our immediate work, out which is of vast moment to the health of a great population in our Indian dominions.

**IS STRYCHNINE OF ANY VALUE AS AN
ANTIDOTE TO KRAIAT, DABOIA,
OR ECHIS POISON?***

By SURGEON-CAPTAIN ROBERT HENRY ELLIOT, M.B., B.S.,
London, F.R.C.S. England, D.P.H.
Cambridge, &c., I.M.S.

Acting Professor of Biology, Presidency College, Madras.

LAST October it was my privilege to read before the South Indian Branch of the British Medical Association a paper on the value of strychnine as an antidote to cobra poison. To-day I propose to lay before you the work, which I have subsequently performed in an endeavour to ascertain, whether the reputed antidote was of any value, in the treatment of the bites of the other common poisonous snakes of Madras, which, as we all know, are the daboia, echis and krait. There is a further point that leads me to address you again, *viz.*, that since the publication of my last paper, a number of fresh cases have appeared. These consist of scattered records in the various journals, and also of a most interesting series of cases by Surgeon-Lieutenant-Colonel JOSHUA DUKE, in his paper read before the Medical Congress last December. I propose, gentlemen, after describing to you the results of my recent experiments, to critically review these different cases:

In order to obtain a stable basis, on which to work, let me premise my remarks, by a few words on the symptoms, etc., of poisoning by the krait, daboia and echis. A comparison of the experiments now discussed with those recorded in my previous paper will shew how strikingly similar are the symptoms of all the various forms of snake-poisoning.

To begin with that of the krait. In this a marked feature is a great tendency to tremulousness, twitching and convulsions, a condition being thus attained, which so closely simulates strychnisation, that in cases, where the nikaloid had been injected, it was at times difficult, if not impossible, to be sure whether the symptoms of motor excitement observed were due to the drug or to the venom. To this very important point I shall again allude later on. Salivation, as a symptom, was conspicuous by its absence, but in some of the monkeys, peculiar chewing movements were noticed, which suggested that the animal had something in its mouth, which it was unsuccessfully trying to expel. Possibly this was viscid saliva.

The typical symptoms of cobra poisoning in monkeys, as described in my previous paper, were repeated exactly in the krait-poisoned animals. I refer to the drowsiness, the drooping of the eyelids, the drunken-like inco-ordination, and the apparent delusions. Where life was sufficiently prolonged, intestinal hæmorrhage occurred. This

was rarely manifested, during life, by blood in the stools, but a post-mortem constantly revealed submucous extravasations of blood, except when the animal died, almost at once, from an overdose of the snake-poison. A subcutaneous jelly-like bloody extravasation around the wound was also a constant feature.

Now as to the symptoms and signs of daboia-poisoning. Here again one finds a tendency to motor excitement as the result of the injection of the venom, but I must confess that this phenomenon was not so well marked as the records of other observers had led me to believe. Nor was I able, in any case by tapping the forehead, or by any sign the animal exhibited, to ascertain the presence of 'the severe frontal headache of viper-bite.' The snakes I used were very fine daboias, and the poison was injected usually about three days after its expression from the dissected glands. The symptoms noticed in a dog bitten by a daboia were precisely similar to those observed in the animals, into which the poison was injected by a syringe. I confess myself at a loss to explain the difference between my own observations and those of other writers, and can only record facts and leave them as they stand for the present. One more point there is, and on this I speak with less hesitation. I refer to the fact that dilatation of the pupil was, in my experiments, very far from a constant sign, whilst others have laid much stress upon it. When the animal survives long enough, hæmorrhage from the bowel takes place, and if life is still further prolonged, most offensive melanic stools are passed. Salivation, though noticed in one case was by no means the rule.

In monkeys, the classical symptoms already alluded to were constantly present.

A very striking point was the extensive spread of the local lesion. The red-currant-jelly-like substance was far more plentiful than in cobra-poisoning. It tracked for a great distance along the lymphatics and apparently also spread directly in the planes of cellular tissue. Even where it appeared to follow the lymphatics, the cellular tissue surrounding these shewed marked changes of the same inflammatory character, presumably from the direct osmosis of the poison through the vessel walls. This venom appears to me to be both more irritative and more diffusible than the colubrine poison.

From the above brief review of the leading symptoms of snake-poisoning, we turn to the consideration of the effect of Dr. MULLER's antidote.

Surgeon-Lieutenant-Colonel D. D. CUNNINGHAM in his excellent paper on this subject, before the Medical Congress at Calcutta, made the following incisive remarks:— "There is one somewhat quaint point in regard to the belief in the efficiency of the salts of strychnia as antidotes for snake-venom. Its adherents seemingly regard these salts as constituting a universal panacea against the action of all kinds of venom. But this implies a belief that in some cases they act homœopathically, and in others allopathically, for in cases of acute viperine poisoning, the symptoms in many cases are those of extreme irritation of the nervous centres, whereas in cases of cobra poisoning, they are indicative of nervous depression. The symptoms of acute viperine poisoning in many cases are practically

* Read before the South Indian Branch of the British Medical Association and sent to the Record for publication.

identical with those of acute strychnia-poisoning, and yet it is strenuously proposed to endeavour to induce the latter in order to save the former."

These words I can heartily endorse, and my grounds for so doing I will now shew you that the strychnised animals died sooner than those which we allowed to cope with the snake poison alone; but this is not all, and to the following point I particularly beg your attention. In this series of experiments I was determined that strychnine should have its fullest chance; accordingly the experiments were made in pairs or in fours, and the venom was equally divided between the two or four animals. In each set of experiments the animal, which suffered first and most severely, was made the control snake-poison experiment, while the animal, which by reason of greater body-weight, greater life-force, or other circumstances, was the slower to feel the effects of the poison, and which, therefore, *ceteris paribus*, would have been the longer in dying, was used for the antidotal test. This method of operating brought out a very striking point, and absolutely supported Dr. CUNNINGHAM's remarks, for in every case, very soon after the alkaloid was administered, the animal rapidly became markedly worse, and as you will see, generally died before its weaker neighbour. I may say that these experiments were carried out before I saw Dr. CUNNINGHAM's paper, and I had the honor independently to arrive, on practical grounds at the same conclusion that that observer's acumen led him to adopt from theoretical considerations.

The weight of the animals were practically identical, they were both in good health, the snake-poison was accurately weighed, and evenly divided between the two dogs. Strychnine was given to one, on Dr. MUELLER's plan of full doses, and the animal whose hap it was to be treated, succumbed to the combined influence of venom and alkaloid.

The remaining animal fought its battle uninterfered with. In twenty-four hours it was as well as ever, and at the end of a week it rejoined its village companions, in decidedly better condition than when it entered my compound! Needless to say I refer the improved condition to regular food, and not to the snake-poison.

While one animal apparently owed its death to the combination of virus and remedy I can confidently state that, from beginning to end, I never saw one atom of benefit derived from the administration of strychnine. In no single case were the symptoms even temporarily removed, and I do not hesitate to say that, while I believe the so-called antidote to be useless, or worse than useless, in cobra poison I go farther, and consider that, with the facts before us, its administration in krait or viperine poisoning must be, if not malpraxis, at least a grave surgical error very difficult to defend. I am aware that I am speaking strongly, but I have chosen my words after careful thought, and in the belief that in so doing, I am discharging a duty, which I may not leave undone.

Now a few words on the echis. There seems always to have been a good deal of dispute about the virulence of the venom of this snake. FAYRE considered it a dangerous viper; some of his correspondents called it deadly, others have thought lightly of its bite. The echis, of these parts, seems to be a much smaller reptile than the specimens met with up North.

FAYRE speak of a fine specimen 22½ inches long. Dr. B. P. BANERJI kindly sent me several specimens, which are considerably larger than those met with in these parts. Out of seven specimens, I have secured here, the longest measured 15 inches. Dr. BROWNING and Dr. HENDERSON tell me that their usual size in Madras does not exceed this measurement. The echis is a very vicious little viper, and can always be relied on to bite at a minute's notice.

I endeavoured at first to extract and inject the poison as I had done with the other snakes, but the combined venom of three specimens of echis was only sufficient to kill two guinea-pigs, and that too after a delay of about seven hours. I accordingly experimented on dogs, making the vipers bite the dogs. In no case did I succeed in killing a dog by means of the bite of a single viper, though one dog bitten by four vipers in different places succumbed in 8½ hours.

With the exception of the local swelling, the symptoms in this case were by no means pronounced. The dog became ill and died, much in the same way as if cobra-bitten, but as it was not closely watched in the last 4 to 4½ hours of life, I would not lay stress on the absence of convulsions, etc.

I may mention lastly an important point which is, that in the course of a talk with a gang of snake-men, I asked if they considered the echis—a specimen of which they had just brought me—deadly or not. They ridiculed the idea of a man dying from its bite, and prophesied that a dog bitten by these snakes would not die, the damage being confined to great swelling of the bitten part. My results amply justified their confidence. In order to prove to me its harmlessness, one man volunteered to be bitten by an echis. I asked each of the four present in the gang, if they would consent to be bitten, and received a willing affirmative in each case. Thinking that they might be "bluffing," and not wishing to push the matter too far, lest they really should be bitten, I gave them another test by saying—'No I don't want to see you bitten by echis, but will you let that snake (a daboi) bite you!' The answer was a most emphatic negative. They began to think me dangerous, so I reassured them by saying that I did not wish them to be bitten by any snake. They seemed a little disappointed, for I believe, that there floated in their minds dim visions of a not unremunerated *atman* cum *dignitate*, within the precincts of my compound till such time as convalescence should be established.

I believe their statement most fully, and I should have no serious fears, were I myself bitten by an echis, but I did not allow their proposition to be carried out, as I think as a stronger case is necessary to justify *cinisation* on man.

With these facts before me, I did not consider it worth while to try the influence of strychnine as an antidote to echis poison; for I am satisfied that the echis, as met with down here is not a deadly snake, and I am unable to obtain specimens from the North. Throughout my experiments with this snake, I have failed to make out either the frontal headache or the dilated pupil, on which some writers have laid so much stress.

I come now, gentlemen, to a discussion of the cases published, since my last paper, and in so doing, I adopt

my old plan of classification. The cases fall under two heads, those in which the snake was identified, as a deadly one, and those in which it was not so identified. The latter being again subdivided into those which show signs of dryophthal poisoning, and those which do not. This is, however, not the classification adopted by all writers; for Dr. DUXE in his paper before the Indian Medical Congress, as reported in the *Englishman* of 25th January, said: "It is a habit and a bad one, where the snake has not been killed or properly viewed, to class recoveries under strychnia as the result of the bite of a harmless snake, etc." I would add a rider to that statement and say—It is also a habit, and a worse one, where the snake has not been identified, and where distinct and undoubted signs of thanatophthal poisoning do not exist, to assume that the snake is a poisonous one, and by including such cases in statistics to absolutely vitiate the value of those statistics." Gentlemen, I leave you to judge which mistake is the more dangerous one. Surely this is the last country where one would accept unhesitatingly a man's statement that he has been bitten by a poisonous snake. Every bite a native receives, in which the offender is unseen in a 'snake-bite,' and every snake a native sees, be it the harmless dryophthal or the deadly daboia, is to him a most poisonous snake.

No case should be included in our statistics, unless a reliable observer identifies it carefully, or unless there is good and clear evidence of thanatophthal bite, such as drooping of the lids, inco-ordination with feeling of drunkenness and drowsiness.

I myself saw a large powerful daboia strike fairly at a dog, hold it, shake it, and only let go, when the dog had fled yelping several yards, dragging the snake along the ground. The part bitten was soft and fleshy, the bite was apparently a fair one, both the glands of the snake, when dissected, though emptier than usual, proved to contain poison. From one gland alone I obtained more poison than another daboia emitted through a leaf in a vigorous bite.

Add to all this, that there was well-marked subcutaneous extravasation around the bite, and the case seems perfect. I was on the point of trying strychnine as an antidote, but fortunately a 'laissez aller' plan was adopted, and the animal, though it became rather ill, did not die.

Eight days later the same animal was fairly struck by a vicious daboia, the bite being almost instantaneous in its shortness, and this time the victim died in less than three hours.

Surgeon-Major BROWNING met with a similar case, and knowing the interest I take in these things, he very courteously wrote to me about it. I will read you his own words: "A healthy cobra bit a dog in two places with no result—Another bite from the same cobra on the same animal resulted in death." Dr. BROWNING also sent me the notes of an interesting case, where a grass-cutting girl bitten by a cobra 18 inches long, recovered with the aid of only local treatment.

Add to these cases the results of the experiments on maddened and you will, I think, be with me, gentlemen, when I say, that in collecting evidence of cure for snake-poison, it is not gold that glistens.

And the most important point, that the case reported by Dr. Duxé was looking at the snake, and not at the symptoms of thanatophthal poisoning. In any case, the signs of strychnine appeared.

In the case reported by A. Marshall, F. R. S., there were undoubted symptoms of snake-poisoning. Strychnine was liberally given, 34 gr. being administered in bulk to a child of 10. No improvement was noted, and the child died. One cannot but notice two points in this case; one is that local treatment is not even alluded to, and the other that strychnine convulsions closed the child's life.

I come now to a case, which has been made a good deal of, in the *Indian Medical Gazette*. To say that it is by no means convincing. Let me draw attention to the following points—(1) Dr. Baker speaks of the snake as a full-grown one, 3 feet long. Full grown cobras run from 5 to 6 feet in length: this was therefore a half-grown specimen. (2) The man was a snake charmer. It is not uncommon practice among these men to extract the poison before removing a fang. This man was engaged in removing the fang, and it is significant that the tooth he was busy on had an empty poison sac, while the other fang, which was *hors de combat* from an old injury, had a full sac. It is at least probable that the man had not emptied the dangerous side before he commenced operations. (3) The symptoms came on slowly, and, as the notes shew us, were not removed by the strychnine. In fact after each fresh injection we learn that there was 'no improvement.' At last after a long continuance of this state of things, the tide turned, and the man gradually recovered. The obvious interpretation seems to me to be that the patient received a small dose of cobra poison, and rallied from it by his own natural powers in spite of the strychnine, which is not proved to have benefited him at all.

Dr. C. A. LAPIENIA's case seems to have been bitten by an echis. The patient struggled on for a day and a half and then strychnine was given. Death closed the scene about an hour after the new course of treatment was commenced.

This case gathers in force when considered along with a case (reported by Surgeon-Lieutenant Colonel H. Myers) in which the patient survived for 24 hours before strychnine was given. Within an hour of the first administration of the alkaloid the man was dead. I do not say that the strychnine killed the patient, and I never in mind that both of them were very ill before the alkaloid was given, but the coincidence is worthy of attention.

In the first of Dr. JORGE's two cases the bite seems to have been undoubtedly inflicted by a cobra. The thanatophthal symptoms are typical of the patient, when admitted, was well under the poison but was not so extremely ill. Strychnine was freely given (145 gr. in 4 hr.), but without the least advantage.

The second case is far less convincing. The snake was only seen by an assistant surgeon, whose daughter had just received a snake bite. The patient, however, showed dangerous symptoms, and was given strychnine. The patient recovered, but the case is not so convincing as the first.

the description, however, the snake is as likely to have been a *Hydrophis*, which closely resembles the krait in appearance, as it is to have been a krait. At all events the krait is not a viper, (the recorder is in error here) but is one of the poisonous colubrine snakes, and as such, would not be likely to have inflicted the four-marked bite described here.

As to the blood that came from the girl's mouth, it may have been due to a local injury inflicted by her teeth in the fit described, which fit was probably due to fright. I have been unable to find any *valid* evidence to shew that Indian viper or krait bite is attended by hæmorrhage from the mouth either in man or animals, though I am of course familiar with the submucous and subserous hæmorrhage of the alimentary canal and lungs found under these conditions.

As to the rest of her symptoms, I think that we shall not outrage probabilities by ascribing them to fear.

Now as to Dr. DUKE's cases. I fear I must differ from that writer in my method of classifying them. As I have already discussed the published cases he refers to, I will not again allude to them, but will confine my attention to his own cases.

They are the most instructive group of cases yet recorded, and had not Dr. DUKE been led to place an undue value on the records of other observers, notably on Dr. BANERJI's cases, I have no doubt that his own experience would have led him to reject strychnine for ever.

To begin with, out of seventeen cases, Dr. DUKE had nine deaths under the strychnine treatment. Of the eight recoveries, he admits that it is doubtful whether the snake was poisonous in 3 cases while in case 14 the offender was a grass green snake, which produced no serious symptoms. I only know one snake in the plains answering to this description, and that is the very innocent and very common *Dryophis Mycterizans*. Four cases remain, I have it on Dr. DUKE's own authority that in none of these cases was the snake brought in for identification. Nevertheless case 6 is unhesitatingly pronounced a cobra bite. We are told that the symptoms were severe, convulsions being frequent. This is in itself a strange history, and one that excites suspicion, for neither in men or animals does one find convulsions as a symptom of cobra-bite till the patient is absolutely moribund. Lastly, I may say that in a letter Dr. DUKE wrote me, he candidly owned, that the evidence on which he attributed the cures in these cases to Strychnine, was his faith in the reputation of the antidote. Science, gentlemen, as I need not remind you knows no such law as faith, and judges on the standard of hard facts. Dr. DUKE's cases read to me thus. In eight of them no evidence is forthcoming of thanatophidial bite and these may therefore be excluded. The remaining nine all died whether from the venom or the remedy or both, it would be hard to say.

To my mind Dr. DUKE's cases are the most damning evidence against strychnine yet to hand, and I think it a high tribute to his integrity of purpose, that in spite of the views he held, these cases were ever put on record. I say, 'held' advisedly, for Dr. DUKE has practically owned to me his conversion from the belief, of which he was the *quædam* champion. I desire to take this oppor-

unity of thanking him for the kindness, openness, and freedom from prejudice, with which he has assisted my enquiries.

Before quitting this subject, allow me to allude to two methods of treatment, which have been recently suggested more or less, as the outcome of the use of strychnine.

The first of these is a custom against which I would raise a most emphatic and earnest protest. I refer to the neglect of 'the ligature' in the treatment of snake-bite. Some indeed have not been content with having left undone the good which they ought to have done, but have gone so far as to undo the good which others had done. I mean that one finds, in the records of cases, instances in which observers, relying on the efficacy of strychnine, have been tempted to remove the ligatures that wiser, if less educated, hands had applied.

I am aware that much latitude must always be allowed for individual opinion in the treatment of any particular case, and I would be the first to give that latitude to any one who keeps within ordinary bounds. Vicious to the patient as I believe the administration of strychnine to be, I can understand the position of those who do not agree with me now, and who therefore administer it, but nothing to my mind can defend the practice of depriving a patient of that refuge from his fate which the exclusion of the snake venom from the general circulation affords. The value of the application of the ligature has been proved up to the hilt by experiment; on common physiological grounds its utility is self evident, and as a method of treatment it has been recommended by names that will live to all time in the history of snake poison research, names such as those of FAYER, WALL and RICHARDS, nay more it has received the approbation of every trustworthy medical officer in this country, who by actions, which speak louder than words, has hastened to apply the ligature as soon as he has reached his snake-struck patient.

Gentlemen, I fear that this example may prove infectious and that many of our subordinates with the best intentions may be led into the same error. It is urgently necessary that we should speak out clearly against this evil and nip in the bud what may otherwise prove a source of danger to the lives we are bound to protect and a source of discredit to the practice of medicine in India.

The other method of treatment alluded to was suggested by Dr. LAUDER BRUNTON. That able writer has proposed washing out the stomach with Condy's fluid in snake bite, on the grounds that (the poison is excreted through the mucous membrane of the stomach and that we are by this mode of treatment able to neutralise it and prevent its re-absorption by the mucous membrane.

There are, however, two flaws in this argument. I speak, gentlemen, with the very greatest respect for the man whom the whole world of science esteems and rightly esteems so highly, and whose pupil I had the honor erstwhile to be. Dr. BRUNTON will be one of the first to yield to facts and two facts face us here.

1st.—You will notice that I found it impossible to poison animals with even large doses of viperine or colubrine poison taken by the mouth on meat. I am aware that FAYER killed fowls by the administration of snake poison

through the mouth, but my experiments which some of you have witnessed have led me to conclusions different from those of that great observer. I may say that Dr. Bowman has also independently arrived at the same result by his work on this subject.

Next.—A reference to the cases in which post mortems were performed will show that the excretion of the poison as evidenced by submucous hæmorrhage does not take place so early or so markedly from the stomach as it does from the lower part of the small gut and from the great gut. Submucous hæmorrhage in these latter portions of the alimentary tube were the rule, while bleedings from the stomach or upper part of the small gut were rare. I am inclined to believe that the excretion takes place through the solitary and agminated patches of adenoid tissue in the bowel.

Obviously, gentlemen, it would be useless to wash out the stomach under these conditions, while it would be a needless source of irritation to the patient who needs above all things to have his strength husbanded that he may be able to fight out his battle for life, unhampered.

The sense of my many obligations again comes over me and I feel my powerlessness to rightly express my gratitude to the many, who have so freely and generously given me their help in my work.

In Madras the Surgeon-General, Surgeon-Lieutenant Colonel ALLMON, Surgeon-Captain THOMSON, Mr. JONES and others have doubled the debt I owe them, while as to Surgeon-Captain GIFFARD, I can only say that much of the work I have put before you, has been his almost as much as my own. Equally generous has been the help I have received from many who are not serving in this Presidency. Of these I would mention Surgeon-Lieutenant Colonel CONNINGHAM, Surgeon-Lieutenant-Colonel JOSHUA DUXE, Surgeon-Captains BUCHANAN and BIRD, and Mr. KANTHACK.

Once again, gentlemen, in closing my second paper on this subject, let me say that I have no wish to make controversies by the sword of controversy. Mine it has been to lay facts before you, and then to leave you to judge each one for yourselves, but I would press home on you and on each one, whom this paper may reach, that the subject we are dealing with is no mere child's play. It is a matter of life and death to hundreds, if not to thousands, and it behoves us to think well, nay more to think our best, and having thought, to throw the whole weight of our influence into the scales on one side or the other.

If erysine be the hope of the snake-bitten wretch, fight for it. If it be a spectral delusion, a shadow of death to rob the living of precious life, and such I believe it to be, away with it, and the sooner the better.

A PHARMACY BILL IN NATAL.

The Natal Parliament has before it a Bill providing for the due qualification of medical men and pharmacists, organizing a medical council and a pharmacy board, restricting the sale of poisons to registered persons under certain precautions. Several members objected vigorously to the monopoly which the Bill sought to create, and the Prime Minister admitted there was much force in the arguments of those who opposed the Bill. It was intimated that poisons used by farmers and stock-raisers, especially, should be excluded from the Bill, and, on the understanding that the Bill in certain other respects should be amended, the Bill was read a second time on the 22nd.

DISINFECTANTS; THEIR ACTION AND USE.

By ROBERT G. B. CHASE, M.D., M.A., F.R.S.E.,
Late Analyst, Calcutta Municipal Corporation;
Emeritus Professor of Chemistry and Physiology
to the Denver (Branch) Medical College; Author
of Water Analysis, Public Health,
Cool Gas, &c.

(Concluded from page 33, Vol. VII.)

CHAPTER XV.

POISONOUS, YET GOOD, DISINFECTANTS.

BURNETT'S FLUID; COPPER SALTS; LEAD SALTS;
LEAD SALTS; LLOYD'S FLUID; SETON'S
LIQUOR, TELEGRAPH BATTERIES, AND
ZINC SALTS; THEIR CHARACTERS
AND USES.

COPPER SALTS.

(498). COPPER SALTS, are useful disinfectants even though they may have the disadvantage of being poisonous and rather expensive.

(499). CUPRALUM is a patent disinfectant of uncertain composition; but which appears to be an aluminium compound containing traces of copper.

(500). SETON'S LIQUOR is obtained by mixing together;—copper sulphate, chromic acid, thymol and boric acid, with a little water, allowing them to stand for several hours; then diluting with a larger quantity of water, agitating every two hours (during the day) for about a week, after which the clear greenish-colored liquid is filtered off and diluted to a proper strength. It is a powerful germicidal, deodorant and does not stain linen or spoil furniture; but it is too poisonous to be used in antiseptic surgery.

(501). COPPER SULPHATE known also as *blue stone*, *blue vitriol* or CuSO_4 , instantly removes the smell of sulphuretted hydrogen and possesses powerful germicidal properties and antiputrefactive powers which make it very valuable for drains, sewers and cesspools but it is scarcely suited for household purposes as it is poisonous.

(502). The waste products of Telegraph batteries may be advantageously employed for disinfecting purposes, their action being aided by the copper compounds which they generally contain.

DONOVAN'S SOLUTION.

(503). LIQUOR ARSENICI ET HYDRARGYRI IODIDI is a very valuable disinfectant and antiseptic; but its corrosive and very poisonous properties are against its general use. It is obtained by triturating 45 grains of Iodide of arsenic with 45 grains of red Iodide of mercury in 1½ ounce of distilled water and then filtering.

LEAD SALTS.

(504). LEAD SALTS form fairly good disinfectants but for some reason or another have not come into general use and though most all the salts are valuable still the acetate is the only one that has up to now been available.

(505). LEAD NITRATE (PbO_2 and PbO_3) rapidly decomposes, sulphuretted hydrogen, becoming converted into the insoluble sulphide of lead (PbS), and setting free the nitric acid that converts animal and vegetable matter into the state of its impurity. It has the same antiseptic properties as lead acetate but should be used with caution as it is poisonous.

is merely a solution of nitrate of silver, prepared by gradually adding 7 ounces of nitric acid to a solution of litharge, worked into a cream with water and then further diluting with 2 gallons of water.

ZINC SALTS.

(508). ZINC SALTS form useful disinfectants even though they may have the disadvantage of being poisonous.

(509). BRANETT'S DISINFECTING FLUID, which is also a caustic poison, is merely a zinc-solution in which 84 ounces of Chloride of Zinc are dissolved in a pint of water.

(509). ZINC CHLORIDE ($ZnCl_2$) is usually used in solution, being exposed either in shallow pans or on cloths that have been soaked in it. Its action is chiefly on the air and it decomposes sulphuretted hydrogen and sulphide of ammonium, while its caustic properties are destructive to organic matter, which it quickly permeates and disintegrates as soon as it comes in contact with it. While in itself odorless the powerful deodorant and anti-putrefactive virtues of chloride of zinc are unquestionable and its antiseptic powers are so great that septic wounds are rapidly rendered antiseptic and its 8 per cent. solution is far more energetic in checking (and purifying from) parenchymatous hemorrhage than is a fifteen per cent. solution of carbolic acid.

(570). ZINC SULPHATE or *vitriol* ($ZnSO_4 \cdot 7H_2O$) is abundantly formed in telegraph batteries by the action of dilute sulphuric acid on the plates of zinc immersed in the battery cells, but as the zinc is generally used in couple with copper, sulphate of copper ($CuSO_4$) is also produced. For analytical purposes it may be prepared by letting pure sulphuric acid diluted to five times its volume of distilled water act upon pure zinc, evaporating the solution to concentration and allowing the sulphate to crystallize out as crystals, resembling Epsom salts in appearance.

(511). The commercial sulphate of zinc is usually prepared by roasting zinc blende (ZnS) at a low heat, extracting with water, concentrating the aqueous extract by evaporation and setting aside for a time to obtain crystals of the sulphate, which are often mixed (during their process of formation) with sulphite of zinc, which does not, however, materially interfere with the action of the sulphate in its uses in the arts or as a disinfectant. Both the sulphate and sulphite of zinc are good disinfectants, especially for sewage where they decompose the sulphur compounds and prevent zymotic development.

IRON SALTS.

(512). IRON SALTS. On account of their cheapness they constitute a rather valuable class of disinfectants but it seems that their very cheapness is against their employment by the general public with whom the adage "cheap and nasty" is carried into operation, without taking heed of remembering that to every proverb and rule there are many strong exceptions.

(513). FERROUS SULPHATE. Known also as *Melanterite*, *Copperas*, *Green Vitriol*, *Iron Vitriol*, *Iron protosulphate*, $FeSO_4 \cdot 7H_2O$ is obtained as fine green oblique rhomboidal (soluble) crystals when iron pyrites (FeS_2) or Marcasite (FeS_2) are oxidized or when limonite acted up by sulphuric acid. It is a common mineral compound. Crystals small quantities of sulphate of cuprous oxide of iron ($Fe_2O_3 \cdot 3H_2O$) which is readily decomposed (yielding a basic sulphate).

on being boiled with water. Cuprous is extensively used in the manufacture of ink and its great tendency to absorb Oxygen ($10(FeSO_4) + O_2 = 2(Fe_2O_3 \cdot 8H_2O) + 4(Fe_2O_3 \cdot 3H_2O)$) makes it a valuable reducing agent and a good disinfectant for application to manure heaps and sewage but as its powers are somewhat limited it can scarcely be termed a powerful sanitary agent even though it has the property of decomposing sulphuretted hydrogen. Exposed to air, whether as crystals or in solution, Ferrous sulphate absorbs oxygen giving a yellowish deposit of ferric sub-sulphate which is readily decomposed by boiling with iron.

(514). FERRIC CHLORIDE, *or chloride of iron* when prepared by treating red-hot iron with dry chlorine is condensed as beautiful dark-green crystalline scales (Fe_2Cl_6) which are highly hygroscopic; but when prepared by evaporating the solution resultant on the action of hydrochloric acid on iron wire and subsequent treatment with nitric acid and more hydrochloric acid it is obtained as pale orange-yellow opaque crystalline masses ($Fe_2Cl_6 \cdot 8H_2O$) which are very deliquescent and freely soluble in water. Through ferric chloride is permanent in air, the feeblest reducing agents rapidly convert it into ferrous chloride. [Thus, $Fe_2Cl_6 + H_2O + Zn = 2(FeCl_2 + ZnCl_2) + H_2O$ or $Fe_2Cl_6 + SH_2 + H_2O = 2(FeCl_2) + 2(HCl + H_2O)$. Ferric chloride decomposes sulphuretted hydrogen and ammonium sulphide and, when used as a disinfectant or sewer deodorant, it yields chlorine to unstable organic matters and becomes itself reduced to ferrous chloride ($FeCl_2$).

THE HISTORY OF PARASITISM AND OF PROPHYLACTIC INOCULATIONS IN CHOLERA.

By SURGEON-CAPTAIN PATRICK HEHIR, M.D., F.R.S.E., L.M.S.

Hyderabad, Deccan.

CUNIOUS though it seem that every disease of alleged bacillar origin has at least half a dozen tribes of micro-organisms saddled on to it, still the parasitic history of the etiology of cholera is now about 46 years' old. POWELL (1849) attached etiological importance to the vibrio regalis, which he found in cholera stools, and WHITE supported this view, while HASEL (1878) attempted to confirm it. Describing the bacilli found in cholera excreta, PASTEUR (1854) stated that they destroyed the epithelial lining of the bowels by multiplying in it.

GIBLL (1856) attributed cholera to a *Proteus* found in the dejects, but the distinguished pathologist HALLIAX (1867) connected it with a variety of micrococci, which he stated were the spores of the *micrococcus*, and this theory was universally believed and for many years quoted in every work on medicine and pathology; but it has since been shown that these organisms are only one of the many varieties found in (human) cholera dejects.

BOUCHARDAL (1868) declared cholera to be due to a virus manufactured by "infusoria," giving rise to a form of fermentation in the soil, and he was of opinion that it was the infusoria in the marshy soil of India, and especially along the shores of the Ganges.

I think the most important investigations in connection with the etiological relations of cholera are those made

conjointly by Professors T. K. Lewis and D. D. CURRIE (1872) and published in their brochure entitled "Microscopical and Physiological Researches into the Blood and Excreta in Cholera," which runs over an enormous field of work. DANET (1873) associated cholera with a cryptogamic parasite which he thought was very analogous to the organisms of acute albuminuria; but differing from it in (a) possessing a more abundant mycelium; (b) being much larger, and (c) the frequent absence of the transverse septa of the so-called "sporiferous cells."

MARTIN and SCHWENINGER (1873), declared that they had found the urinary tubercles of cholera patients completely blocked up with bacilli, and HAYEN and RAYNARD found the same thing, but did not attribute the cholera to them; whereas DWAINES considered that three species preponderated, *viz.*, vibrios, bacterium and bacteridium. Statements like these are of no value, because, ordinary dejecta swarm with most varied microorganisms of both the animal and vegetable kingdoms.

Almost every text-book on medicine written in Europe or America tells us that all of Koch's statements have been repeatedly confirmed, but never directly refuted by the many authorities, who have investigated these matters, and we are similarly assured that in every case of genuine Asiatic cholera the comma bacilli are present in the intestines, and that they are never found under other circumstances. This we allow to be so in the vast majority of cases, but giving the fact its maximum value, it is only an interesting clinical and diagnostic point for differentiation in doubtful cases.

True REITSCH and NICOTÉ followed by KOCH himself, succeeded in producing cholera in the guinea-pig by introducing pure comma bacilli into its duodenum. But this does not prove that the comma bacillus is really the specific cause of cholera in the human being, nor that the spirillum is invariably present, nor how it gains access to the human system, or in what manner excites the characteristic processes of the disease.

The rapidly increasing number of organisms of this kind met with in the human being led LEUCKART to clear the large class of organisms now embraced under the term *sporozoa*, a definition we cannot accept, because it excludes a certain number of the very forms for which the generic name *sporozoa* was created on account of their chief characteristic sporulation.

As my prediction of five years ago has been fulfilled that parasitism from protozoa would become an important factor in the pathology of human disease, I feel sure that in the years to come, organisms of the animal kingdom will be found to play a much more important part in the etiology of disease than we can even at present conceive. Sceptics may jeer, and enthusiasts exaggerate, yet the rôle of animal parasitism, in the introduction of poisons into the human system, goes on yearly increasing at a terrific rate and though strongly tempted to reply "None" when asked, the precise connection of parasites with disease, it would be safer to say we are only on the verge of proving the connection of at least five such maladies with such organisms. First amongst these I would place the

whole of the malarial maladies as they make up about half of the aggregate cases coming under consideration in India. In the next group I would put cholera, dysentery, erysipelas, pyæmia, septicæmia, carbuncles, small-pox and hydrophobia.*

In the pus of one variety of furuncle, I have on several occasions met with an actively multiplying protozooid body, I have also met with different sorts of spores in some form of: (1) *simple colitis* giving rise to symptoms exceedingly like ordinary colic, but more chronic and less intense; (2) suppurative *odontitis* giving rise to molecular disintegration of the periodontum and the crusta petrosa of the teeth, finally causing atrophy of the alveoli, and falling out of the teeth; (3) *aphthæ* of children, cachectic subjects, and old people, (4) *vesical catarrh*.

It is now more than 15 years since the parasite of malaria was discovered by LAVERAN, and the curious part about the literature of the subject is, that there are two distinct schools at the present day: one entirely following LAVERAN's theory of malaria and the other the Italian school, believing that the organisms are distinct and different, and that there is no identity in the details of the polymorphic organism discovered by LAVERAN; and those recently described by MARCHIAFAVA and BIGNAMI, except that they all belong to the same class of parasites. I verily believe that the parasites described by LAVERAN in Algiers and by GOLGI, MARCHIAFAVA and DAMLOSKY are precisely the same as those that we see in this country and are undoubtedly met with in the blood of different cases in India.

From my own observations on the hæmatæzoon of cholera, the plasmodium malarie, the bodies met with in amoebic dysentery, I conclude, that in the life cycle of pathogenic amœbi, we arrive at certain general facts, the chief of which are:—

1. That all pass through the stage of development markedly distinct from one another.
2. That these stages are covered in (a) impregnation of cells or tissue, or some structure with spores; (b) the formation of cysts, and (c) the development of the mature parasite.
3. The manner of formation of spores differs in different species, but in all may tend to the stage of sporulation.
4. The formation of cysts is a special feature, and may be termed the cyst stage.
5. The development of the flagellæ, spherical bodies may be formed in the plasmod stage or stage of maturation.

Whilst contained within the cysts the amœba present first a hyaline and then a granular appearance, but their position is limited on the outer surface by a smooth or wavy border, but the inner surface is smooth and uniform. In the amœboid stage the organism may be at once recognised by its granular contents.

The proof as to the etiological significance of the comma bacilli is as yet to come, and though I do not

* In one case of hydrophobia I discovered a minute, ellipsoid animalcule, structure meeting with solution difficulty and entirely different to any and dissimilar.

as a critic, yet the fact of my having devoted a great deal of attention to all that concerns the subject of cholera qualifies me to express an opinion upon the question of HARKNESS, whose researches are valuable if it be proved that the comma bacilli is not the cause of cholera, and we are left in the sorry plight of ten years ago, while if we go on giving blind heed to improved doctrines, we shall be in the same place 10 years hence.

The process of prophylactic inoculation against cholera has had a most chequered career; beginning with FARRAN'S inoculations under very primitive and insufficiently recorded conditions, whilst cholera was raging in Spain. Certain details given through Mr. (now Sir) CHARLES CAMERON M. P., tending to shew that it might be possible to ward off the fatal effects of the disease, a test experiment was made by DR. FARRAN at Alieria, a town of about 16,000 inhabitants near Valencia. Subsequently two special scientists, Messrs. PAUL GIBIER and VAN ERMANGEN, who were appointed by their respective governments to study DR. FARRAN'S method of preventive vaccination for cholera, (independently) arrived at the conclusion that inoculation with his cultivated virus (of the comma bacillus) *did not prevent animals operated on from taking the disease*, when the poison is experimentally introduced.

Professor RAY LANKSTEN maintained that KOCI'S comma bacillus is merely a segment of a spirillum, that has broken up into little pieces, each of which corresponds to a turn of the spire. This is partly true, as certain cultivations appear as long spirilli, but most of them remain throughout as commas.

M. POUCHET'S contentions have been borne out by experiments at Marseilles, shewing that biliary acids are relatively more abundant in the blood of cholera patients than in others. When DR. FARRAN'S experiments were subsequently subjected to careful re-investigation, it was specially shewn that the primary data upon which all his figures and conclusions were based were faulty. And had he really been convinced of the value of his own work, he would not have been discouraged by such opposition which was also on every side offered to LAVRAN'S discovery of the plasmodium malarie but the latter was so convinced of the value of his discovery that after a six years' fight he succeeded in converting almost the whole pathological world to his views.

Next followed Professor GAMALIA'S inoculations, which died a natural death, though, at one time it was actually decided that he should come out to India and practise his system as HARKNESS is doing at the present moment, but for some private reason, he relinquished his intention. And we have not heard whether his prophylactic inoculations were practised during the last fierce epidemic in Budapest, where he had every opportunity of proving his claims. The success of HARKNESS'S method of inoculation appears to have been due partly to the fact of his being a foreigner working in the midst of Englishmen, and partly to the natural desire of doing anything which will give the people a guarantee against attacks of this dire scourge, but chiefly to the belief expressed by a few influential medical officers in KOCI'S comma bacillus, and results obtained from work based on that parasite.

Against the principle of prophylactic inoculation I have nothing to say; as I believe it to be a system which, alone or in combination with anti-toxines, will perfectly revolutionize the sciences of preventive medicine and of therapeutics as proven in diseases, such as anthrax, hydrophobia, pleuro-pneumonia, &c. It is a field of research practically illimitable in its sphere of usefulness, and what has been proved in the case of some specific diseases will be proved of others. Always and provided that at the outset of such experimental work we are dealing with the true cause of the disease, the real *contagium vivum*—if such there be,—and not with an agent which has been forced into a false position by those who have had but scanty opportunities of testing the accuracy of the doctrines they promulgate. It is easy for adverse critics to pick holes in the bacteriological work of the present day, because it is an undeveloped science—in process of evolution, and the maturity of which may probably not be attained for some generations to come. The same may also be said of the theories of ptomaines, leucomaines, immunity, &c. But few of those who oppose, bacteriologists are eligible to express an opinion upon what they know but little about.

I believe that the time is not distant when prophylactic inoculations will be practised on a wider scale, with more successful results in a number of specific diseases, than they at present are. It is highly probable that we shall, by and by, have a commission to decide on the merits of HARKNESS'S inoculations as a prophylactic measure against cholera, when those who are interested in its being considered a success or a failure, will be asked to give an opinion upon the subject. We should be disposed to ask perfectly independent and trained scientific bacteriologists to do this, and especially men who, whilst they have had some experience with cholera, and are perfectly familiar with all the conditions necessary to conduct, are not prejudiced by exposing either side to such an investigation.

When Professor DUMAS (1869) requested PASTEUR to investigate the silk industry in Southern France, the modest savant complained that he knew nothing about sericulture. "So much the better, said the great physicist, you go with an untrammelled mind." Within three days after beginning this work, PASTEUR had solved the whole problem of the prophylaxis of flacherie.

It may be remembered that KOCI'S main contention is that the comma bacillus is invariably met with in the dejecta or alimentary canal of cholera cases, and from this fact a diagnosis in any doubtful case may be settled by finding the organism in the stools and vomit. But negative results from simple microscopical examination do not exclude cholera; while KOCI himself allows that this examination is only successful in 50 per cent. of cases. In the other 50 it can with possible certainty be settled only by cultivation experiments followed by microscopic examination.

In the same way we are able to separate various kinds of toxopeptones from putrid meat, the separation being effected by alcohol which precipitates them, whilst they may be afterwards extracted by means of pure (distilled) sterilised water.

KIMURA was the first to show that the serum of animals recovering from an infective disease has the

peculiar property of giving immunity against the infection of that disease, when inoculated into other animals of the same class. He states that he has proved satisfactorily that the blood serum of patients recovered from cholera renders to guinea-pigs immune to the infection of the comma bacillus. But this conclusion was scarcely consistent with his previous statement that the serum of many human beings, who never had cholera, when inoculated into guinea-pigs, renders the latter immune from infection with the comma bacillus. It is only recently, however, that it was proved that the serum of 20 per cent. of all cases gives immunity against the infectivity of the comma bacillus, although the minimising power of the serum does not necessarily exempt the donors (of the serum) from this infectivity. Further, it is shown that the serum of those suffering from cholera gives similar immunity in 20 per cent. of cases—a fact which confirms the statement that the immunity given by the serum is no test of the extent to which the donor of the serum is himself rendered immune from cholera. After death from cholera the serum in 50 per cent. of cases possesses protective properties, whilst the serum of recovered patients only 58 per cent. gave immunity to guinea-pigs. We therefore see that the difference between 50 and 58 per cent. of protection given by the serum of the non-cholera, and the recovered persons is so small, when allowance is made for experimental errors, that it may be neglected, and the conclusion is forced upon us that there is no immunity gained in the guinea-pigs by the inoculation into them of serum from those who have had an attack of cholera.

It is also proved that guinea-pigs die when the comma bacillus are injected into the peritoneal cavity. The injuries produced by injection do not depend on any form of intoxication from intra-cellular or protoplasmic form of the comma bacillus, but are a true infection. This is shown by the fact that post-mortem comma bacilli are found in enormous numbers in the peritoneal cavity and in the blood, whilst the bowels are but little, if at all, affected. An agar-agar preparation injected in the same way causes only slight fever, and cultivations exert very little effect, although the strength is regained if treated with fresh agar-agar. When living eggs of the domestic fowl are inoculated with virulent comma bacilli (known as HAREFFA's method) the albumen becomes extremely virulent, four c.c.m. of it being sufficient to kill a guinea-pig in about a quarter of an hour. Attempts to isolate the toxin from the albumen failed, but a toxo-globin and a toxo-peptone were found, the latter having far greater virulence than the former. Aerobic cultivation of the comma bacillus in pure peptone solutions led to the production of two peptones, one of which resisted the influence of boiling, but was less poisonous than the other which killed guinea-pigs in 7 minutes, and was utterly destroyed by exposure to a boiling temperature. If aerobic egg-cultures are made, a peptone is formed, which does not kill, though it caused indigestion in guinea-pigs, and was not readily destroyed by heat. From these data it is presumed that an aerobic growth favors the formation of cholera-toxin of the comma bacillus. Egg is the best medium for

their culture, but the medium for the growth of the comma bacillus, and not from albumen, as is usually supposed. This experiment is of great importance, and has very important bearings on HAREFFA's statement when he made his statement to the effect that it is difficult to get a strong poison (virus forte) and that this can only be done by its passage through guinea-pigs.

Again, there is considerable interest attaching to the fact that we cannot transmit the cholera infection directly from animal to animal uninterruptedly; that is, by injecting the peritoneum of one guinea-pig into another, at once or later the process of infection ends, and the animal infected does not show any signs of being unwell, or scarcely evanescent indications of indisposition, although the infecting agency may be teeming with the comma bacillus. If agar cultures are prepared from this innocent substance, the full virulence is regained. This shows that the interrupted passages of the comma bacillus through the body of animals reduces the virulence of the comma bacillus to zero, this micro-organism becoming then prophylactic instead of pathogenic or parasitic. When they have lived in this saprophytic state for a brief period, however, they once more become pathogenic.

Rabbits and dogs, it is said, have been immunised against cholera injection by various ways, (especially by means of injections of sterilised or albuminoid virus or immunised *per os*, and proved that the serum of such animals has great protective powers. To apply such experiments to the introduction of prophylactic measures, attempts have been made by means of intravenous injections, and it was found that their serum proved bactericidal to the comma bacilli *in toto*, and also apparently decomposed the cholera serum outside the body in the test tube. The immunitive and curative powers of such serum were said to be very great, and it is argued therefore that such serum might with hope of success be employed on persons already suffering from cholera. It is believed by some that the serum contains an antitoxine which acts as a preventive principle, and it has been separated in the dry form, and found to be as protective as regards immunising power as the serum itself. But if we view these points in connection with the experiments of MATSONIKOFF, already quoted, we find that they lose ground. The whole of these considerations point to the fact that we have advanced very little as regards our knowledge of the actual etiology of cholera. How then is it possible to be so full of expectation from the anti-choleraic inoculation of HAREFFA?

The only direct proof that these circumstances give us is that the comma bacillus, under certain conditions, is capable of producing cholera in the guinea-pig; (2) that the serum of human blood immunises them; (3) that the virus, after having passed through the guinea-pig, loses the greater part of its intensity, and that if guinea-pigs are inoculated with the reduced virus, they are protected for a certain length of time from the action of the comma bacillus.

At their best such experimental inoculations as those practised by HAREFFA are very of temporary value. It would be interesting to know if it is only an experiment, and not a fact, that much beyond negative evidence, and even beyond this kind of evidence, these inoculations, should be carried

in districts where cholera is at present in the endemic form.

It is a strange circumstance that the unfortunate people of India and our soldiers should be made the victims upon whom to perform an experimental procedure of this kind, and that simply to gratify the curiosity of a few scientists, who believe devoutly in a process unsupported by such problematical hypothetic and equivocal evidence as that under consideration.

But if it were possible to concede a single advance to these inoculations, we should still have to face the difficulty connected with the question of the length of time over which the protection lasts—only for a year, and then destruction. We must be inoculated yearly. It is not likely to last for many years, because of the little disturbance it produces. I do not express this last statement as a general doctrine, although there may possibly be an element in it for which we may at some future date be able to generalise.

A MIRROR OF PRACTICE.

HYSTERICAL DYSPHAGIA.

BY ASSISTANT SURGEON A. BEALE I.M.S.

Medical Officer in charge R.I.M.S. "Clive"
Southampton.

At Southampton on the 29th of June 1895, a lascar reported to me that he could not partake of his meals, or even drink anything for the past 24 hours. On examining the inside of his mouth and throat the parts were found relaxed, and very slightly injected. The index finger of right hand was introduced as low down the throat as possible but no obstruction could be made out. On external palpation of the neck, which felt soft but looked rigid and its superficial veins distended, he winced saying that it was painful; nausea and vomiting were also observed. I could not understand what prevented his swallowing, as everything appeared natural enough. His eyes were injected, starting out of his head and full of tears. I fancied he was malingering, and, to be on the safe side, offered him a draught, containing 3ss each of Pot. Bromide and Spts. Ammon. Aromatic, which I got him to swallow in very small quantities at a time, but with great difficulty. The next morning his temperature was 99, and dysphagia no better—would partake of neither food nor drink—viscid saliva accumulating in throat, in great quantities, injected eyes, lachrymation, pain in throat with venous distension, peculiarly offensive breath, brown tongue, starvation, constipation, prostration, extreme nervousness, with an accentuation of distress on attempting to swallow anything, were the signs present. Towards evening the more urgent symptoms abated and the constriction relaxed. The following day he was apparently cured, for he could take liquid nourishment, and all his nervous symptoms had completely passed away except the pain in throat (on slight pressure) which however soon left him.

Treatment consisted in—Frequent Candy's mouth wash. Pot. Brom. gr. 35, three times; Rhusky 4-oz. thrice; nourishment in such quantities as he could be made to take; and Magnesia Sulphate.

Now this disease I was inclined to associate with a variety of similar affections, for instance diphtheria, hysteria, hydrophobia, obstruction of œsophagus, &c. whose enumeration of each of which I give by way of comparison. It resembled the first named disease by there being rather high fever; head, heavy painful and heated; brain, dull of quick perception; frequent nausea and even vomiting; mucous membrane of throat, red and very painful, rendering deglutition difficult—the peculiarly offensive breath was not to be overlooked as being suspicious—brown tongue, constipation and prostration, being the principal remaining points of resemblance. Of course the disease being brought early to my notice I did not expect to so soon see developed the characteristic white patches of diphtheria, but still I expected they were to come. When laid side by side with hysteria there were many symptoms which pointed the case out as being very much of this nature, as for instance the nervous phases, lachrymation, imaginary pains in throat, the loss of power of swallowing which in reality meant the condition known as globus hystericus, and the headache. Compared with hydrophobia we had the following points of resemblance—headache and fever, spasms of muscles of throat, which felt hot and choking and exhibited a condition of dysphagia, the nervous distress and tremulousness excited on offering him drinks—the copious secretion of viscid saliva, and prostration.

His condition I again thought very much like what would be present in obstruction of the œsophagus, lower down than the parts into which I could see or feel, and brought on possibly by the formation of an abscess, impaction of some extraneous substance, or by pressure from adjacent parts within—Before closing I will introduce the principal factors which induce the state known as dysphagia or difficulty in swallowing, which may arise through many causes, as disease of tongue, fauces and œsophagus, it is a symptomatic as well as sympathetic affection—Seldom exists of itself. It may be seen in cases of paralysis, contraction of the œsophagus by cancer, abscess, stricture, ossification, aneurism, bronchocele and foreign bodies. The sympathetic variety is seen in hysteria, tetanus, trismus, and hypochondriasis.

In the idiopathic variety are seen elongation of the uvula, with relaxation of the œsophagus and pharynx. Of course the previous history, when comparing the signs of similitude which existed between the case under treatment, and the diseases which it resembled, enabled me to fix the affection as being purely hysterical in nature.

TWO CASES OF PUNCTURED WOUND OF THE CHEST WITH INJURY TO THE LUNG: RECOVERY.

BY ASSISTANT SURGEON M. G. DESAI, L.M.S.

Malespore.

C. J., a Hindu male, aged 33, was admitted into the Brooch-Civil Hospital at 4.45 A.M. on the 21st February 1898.

History.—The patient states that at about 3 A.M. some one entered his house and extinguished the lamp. Hearing a noise like the opening of a lock, he got up and tried

to light the lamp, but while striking a match, for this purpose, he was wounded in the chest by some one thrusting a sharp pointed instrument into him. He rushed down stairs, cried out for help, and lay down on his verandah.

Present condition—Has an incised penetrating wound, $2\frac{1}{2}$ inches long and $\frac{1}{2}$ inch broad, on the upper part of right infra-axillary region, but rather curved with its concavity looking outwards and upwards. The chest has been penetrated into the 4th intercostal space on a level with the nipple, and, the lung and pleura being injured, blood and air-bubbles escaped from the wound when patient coughed. The wound extends from above downwards and without, towards, its lower margin corresponding to a line on a level with the right nipple and lower part of the anterior fold of the axilla, while the upper margin is situated in the middle of the axilla—midway between the anterior and the posterior fold. Pulse very weak. After plugging with lint and boracic wool and staunching the bleeding, the wound was dusted over with iodoform, a drainage tube introduced through the wound into the pleura, the external wound was sutured, iodoform dusted over the part and the affected side of the chest strapped with adhesive plaster.

R. Extract ergot liquid mxxx
Aqua ℞ix

One-third part every 8 hours.

2-30 P.M. Temperature 100° . Pulse 92 and weak, complaints of pain in the chest, no bleeding.

The sutures were removed on the 23rd instant, when healing began to take place and on the 10th March the patient was discharged with only a small skin wound remaining. There was very little trouble during convalescence.

CASE II.—DUALA a Mahomedan boy aged 9 years was gored by a buffalo, just below the lower angle of the left scapula, at about midday on the 19th of October, 1894. When brought to the Malegaon Dispensary at 2-30 P.M., the wound was $1\frac{1}{2}$ inch long, but there was no bleeding. During each respiratory act a quantity of air was sucked-in and expelled from the wound, and the skin, to the extent of about 2 inches, acting as a flap right round the wound. The skin wound was on the 8th intercostal space while the deep wound, opening into the lung, appeared to be in the 7th intercostal space. Body warm, pulse 100, Respiration 28.

The wound was dressed with corrosive sublimate solution, a drainage tube inserted, Iodoform was then dusted on the part and the chest bandaged.

Ten minims of Liquor Morphie Hydrochloratis were given.

The boy had no bad symptoms. The temperature generally kept to 100° and the respirations gradually fell to 24 till the 2nd November when the temperature rose to 102° in the evening, the pulse to 104 and the respirations to 44. On examining the chest nothing abnormal was found.

On the 2nd day after admission the bandage was replaced by strapping adhesive plaster to the affected side. The boy was given quinine mixture since admission till the evening of the 27th when, on account of the high temperature, diaphoretic were given. From the third

the child had no fever, the respirations fell to 20 and the general health seemed to improve. The drainage tube was removed on the 6th. The child made a good recovery without any untoward symptom and was discharged, cured, on the 23rd November 1894.

A CASE OF MELANA.

By BANKIM BIHARI CHATTERJI, L.C.M.S.

Bali.

At 11 P.M., on the 8th of July last, I was called in to see a boatman, belonging to the salt Police Establishment, Bali, who was practically healthy, save that he had a slight enlargement of the spleen. He was a well-built man but a habitual ganja smoker, and before I was called in, had passed about some thirty stools of a dark color and somewhat bloody. I found him lying semi-comatose with sunken-eyes, cold extremities, sub-normal temperature, at intervals, cramps of the muscles, pulse thready at the wrist, great thirst and vomiting, but no hæmorrhoids nor tenderness over the abdomen.

I prescribed the following:—

R. Bismuth subnitrate gr. x
Acid gallic gr. v

M. Ft. Pulv. one every 2 hours.

R. Tinct. digitalis 3ss.
Acid sulph. dil ʒss.
Hazelgæ ʒi ss.
Spt. chloroform ʒi ss.
Aque anethi ad ʒvi

M. Ft. Mist. 6 marks one every 3 hours.

Ice to suck *ad libitum* and Empt. sinapis over the epigastrium.

9th July, 6 a.m.—Temperature still subnormal. Pulse 116 and full, comatose, thirsty, but the stools were fewer and less bloody; no urine.

The same mixture and powder continued. Port wine ʒii for a dose to be mixed with arrowroot and ice and taken every four hours.

In the evening he was better, pulse full, 100, conscious, passed urine, vomiting still, body and extremities hot.

R. Bismuth subnit. gr. x
P. creta aromat. gr. x
M. Ft. Pulv i.

Sig: To be taken every 2 hours.

R. Spt. am. aromat. ʒi
Spt. chloroform ʒi
Tinct. digitalis mxxii
Tinct. opii mxx
Acid sulph. dil ʒi ss.
Aque anethi ʒvi

M. Ft. Mist. 6 marks, one every 3 hours.

10th July—Quite conscious, temperature 97° F, pulse 96, no stool, complaining of weakness.

Remarks.—I submit this case not on account of its rarity but to call attention to:—

1. Rallying from extreme collapse.
2. In this season of the year, the people of this locality suffer from gastro-intestinal disturbances producing diarrhoea, dysentery, cholera and melana, all caused by the muddy river water, used for drinking. Sometimes the cases prove fatal. The best plan of treating these cases, in the mild form, is to give a dose of castor-oil to clear off the offending materials, while astringents are harmful.

*Sulphuric acid and Spt. Am. Aromat are not incompatible; either the ammonia or the acid should be first dissolved in water.

DIET CURE IN OBESITY.

By V. S. BALASUNDRA MUDALIAR, C.M.S.

In January 1886, when a gentleman twitted me about growing "stout," I was 25 years of age, 5 feet 5 inches in height and weighed 154½ lbs. which was therefore an increase of 7 per cent. on what I should have been by DR. TANNER's theory which gives a mean weight of only 142 lbs. to my height. Having no hereditary tendency to corpulency, I became naturally curious and consulted books treating on obesity, diet cure, and fruit diet as devised by Drs. T. L. NICHOLS, L. ENSMORE, GRAHAM, TRAIL and Mr. BANTING, &c.

My usual diet was a mixed one, rice forming the staple article, but I now avoided taking fatty (ghee and oil) carnesous, saccharine and starchy foods and adopted light meals, twice a day, of vegetables and fruit and drank a little water when thirsty. I took exercise and a hot bath daily and slept only 7 or 8 hours at night. By this plan I reduced myself to 109 lbs., being changed from my former ungainly condition to a thin person. I however enjoyed health, vigour and activity till my friends interfered and persuaded me to return to my usual diet when alas my obesity returned.

The following table will shew the reduction in my bodily weight at different periods and its increase after I resumed my usual diet.

| Date. | Weight | Date. | Weight |
|------------------|--------|------------------|--------|
| 14-1-86 ... 154½ | | 10-8-87 ... 117 | |
| 15-2-86 ... 149 | | 22-8-87 ... 116 | |
| 27-2-87 ... 146 | | 23-9-87 ... 112½ | |
| 23-4-87 ... 139 | | 26-10-87 ... 109 | |
| 19-5-87 ... 133 | | 7-8-88 ... 137½ | |
| 24-5-87 ... 136 | | 18-7-89 ... 157 | |
| 30-5-87 ... 133 | | 11-3-93 ... 123 | |
| 17-6-87 ... 131 | | 3-6-93 ... 171 | |

SCORPION STING: TOBACCO TREATMENT: RECOVERY.

By J. N. S. COOPPOO SAWMY, M.H.A.

Fort, Trichinopoly.

A FEMALE relation, aged 17, was stung by a scorpion on the left great toe at 8 p.m. on 6th January. At 8-30 p.m. I found her in the following condition: Prostrated, frothing at the mouth, eyes half closed, hard breathing, was conscious, creeping pain all over side of the body and the left lower extremity, pulse weak, cold sweat over the left foot and leg—on the whole she was restless and very low.

Treatment. I had no medicine whatever with me as I was on leave, nor I could procure any from the Civil Hospital at that time of the night, so I gave her some brandy and water, and searched carefully for the sting which could not be found, I also rubbed garlic, into the spot, but it gave no relief to the poor woman. The father of the patient then sent for one of his neighbours, an old man, said to be a curer of scorpion stings. He brought some leaves belonging to the "Atropaceae" and making them into a small bundle in a cloth, which he soaked in water for a few minutes and then squeezed it into the nostrils of the patient, who was made to sniff up the juice, about 30 minims, being placed in each nostril. After a few minutes the symptoms, above mentioned, gradually disappeared, but there was nausea and vomiting, which continued till 12 p.m., and the patient recovered some two hours afterwards.

THE Indian Medical Record.

16th September, 1895.

SOME GENERAL OBSERVATIONS ON THE REPORT OF THE ROYAL COMMISSION ON OPIUM.

WE have in previous articles at some length reviewed the medical memorandum by Sir WILLIAM, ROBERTS who was medical expert with the Royal Commission on Opium. We now turn to the Report of the Commissioners, and as we proceed, it will become apparent that the same bias, the same kind of questionable and unreliable evidence, the same perverted obliquity are found here which we saw characterised the Medical Memorandum.

The nature and conclusions of any report which would emanate from a body of Commissioners whose opinions were necessarily founded on evidence almost entirely supplied by official and interested witnesses was a foregone conclusion. If the Commission had been asked to frame their opinions on the opium habit in India from the bulk and not from the quality of official evidence, or even from the unanimity of official witnesses who constituted the vast majority of witnesses examined, then their way was clear. The conclusions could have been written by the India Office in London, and thus saved the expense of a Royal Commission. There could be only one verdict on the examination of such witnesses, and that would be in complete agreement with the views and policy of the Government of India. But a Royal Commission should be, above all things, impartial, discriminating, and loyal to the kind of evidence placed before it. It could not be expected to be so, if only the official side of the question was presented by witnesses whose future official promotion and social status might depend upon the kind of evidence they tendered to the Commission. It has been well said, that in this enquiry the Government of India was on its defence: or as LORD BRASSEY candidly admitted to the Secretary of the Anti-Opium Society in Calcutta: "We all appreciate that in the encounter in which you are engaged with the Government of India upon its own ground, you are placed in circumstances of no ordinary difficulty." That the Commissioners have not, in considering the official evidence laid before them, made sufficient allowance, for that fact is abundantly evident throughout the report. Instead of discounting the official evidence, they actually emphasise it as the most important evidence laid before them, entirely ignoring or discrediting the disinterested evidence of an influential portion of the non-official national community, and the conscientious and discriminating testimony of missionaries—medical and clerical—whose knowledge of the people and their habits is not equalled by any branch of the public service. The following extract from the report indicates how the Commissions were influenced by the official witnesses. In Section II, para. 58 of the Report we find the following—"No part of the evidence deserves more attention than that of the medical witnesses. A large and important section of these were members of the Indian Medical Service, and we naturally attach great weight to their testimony." This was anticipated by

the Government, and consequently medical witnesses, who had never given any attention to the subject, were summoned from remotestations at great expense, to give evidence at Calcutta. In some instances medical officers whose stations were close to the centres where the Commission sat to hear evidence were summoned to Calcutta as if the Government were deliberately determined to increase the expense of the Commission at the expense of the Indian taxpayer, in order to make the Commission unpopular with the people of India. In short the powerful machinery of a great empire was set agoing to defend and bolster up a traffic which was looked upon in official circles as the very life-blood of the Government of India. It was early foreseen by those interested in the subject in India, that the composition of the Commission itself composed and officered largely by officials boded ill for an impartial, independent and open enquiry. The English Members of Parliament, although in the main honest and upright men, with a sincere desire to act impartially, were yet inexperienced as regards Indian questions and consequently were no match for the official and ex-official element on the Commission. The whole drift of the Report shows that it was carefully and skilfully framed by able officials who knew just how far the non-official members could see, and how far it was possible to lead them without rousing their suspicions that they were being misled. The members of the Commission, however, cannot be said to be unanimous in the adoption of their Report. There is at least one able dissident, in the person of Mr. HENRY J. WILSON, M.P., whose "minute of dissent"—a clear forcible statement printed together with the Report—will, in all future time, shew the very questionable methods by which the Government filtered the evidence before it reached the Commission, and which must detract from its value as a reputed spontaneous expression of Indian opinion regarding opium. The dissent published by Mr. Wilson contains an exposé of erroneous and misleading statements made—not wantonly, we are prepared to concede—by officials. Such statements should invalidate every part of the evidence tendered by those witnesses; but as far as we are able to judge, they do not appear to have detracted one jot from its value in the estimation of the Commissioners.

Of the 722 witnesses examined by the Commission 181 were anti-opiumists, 487 pro-opiumists, and 44 were neutral. The anti-opiumists were made up of qualified non-official medical practitioners, medical and other Christian missionaries, and the majority of the native journalists, lawyers, teachers and professors. The pro-opiumists represented the great majority of the official classes, European and native, including military medical officers, together with many titled personages, as land-owners, and persons having financial interests at stake. This analysis will justly raise a suspicion, at least, of the direction which it was desired the evidence should take.

"Persuasion" or coercion used to induce ryots to cultivate opium.—Mr. Wilson begins his examination of the evidence set before the Commission at the opium cultivation question and he finds that in order to induce the ryots to cultivate opium, persuasion is used, which would mean in English "compulsion." This "compulsion" was greater in the beginning of the century, and the process by

which the ryots were induced to cultivate opium was called by the ryots "coolie driving," which he interpreted as "collecting" the cultivators. Mr. Wilson does not recollect this kind of "coolie driving" with the same anxiety of the ryots to obtain the great privilege of cultivating opium.

Proof that the cultivators were underpaid.—But for most conclusive evidence on this subject is furnished by what has happened since the Commission left India. The Indian Revenue Department's Resolution No. 2204, 20th April 1894, comments on the decrease of the area of cultivation, giving among other reasons the competition of other crops, and states that the price of opium paid to cultivators will have to be increased in order to keep pace with the rise of prices of other produce. In accordance with this the price paid to the cultivators has been raised 90 per cent., viz., from Rs. 5 to Rs. 9 per seer. This proceeding in the present straitened condition of Indian finance, is in curious and suggestive contrast with the official evidence presented to the Commission as to the profitable and therefore popular character of the poppy cultivation.

"Pressure" brought to bear on cultivators.—It was proved and admitted by Mr. FORBES, Commissioner of Patna, that a native zilladar, a Mr. CHRISTIAN, Sub-Deputy Agent, and Mr. SKRINE, the Collector of Bhagalpore, were guilty of bringing "pressure" to bear on the ryots in order to induce them to cultivate opium; and we have not heard that any of those officials have even been censured for such apparently every-day conduct.

Exactions practised on the opium cultivators.—Exactions of every kind are practised by the zilladars and subordinate officials on the ryots; and it was inferred that even European officials were not above suspicion. Crops were ruthlessly destroyed by opium officials when they suspected that opium was not sufficiently grown by the ryots; and in cases of real or supposed infringement of opium law, "departmental punishment" was inflicted on offenders, instead of sending them up to the criminal courts. This kind of "punishment" is apparently approved of by the Government of Bengal.

The compensation babbie burst.—The hue and cry raised about the question of compensation to cultivators, should they be forcibly forbidden to cultivate opium, is quite a new idea—an after-thought on the part of the Government. The suppression of opium cultivation by the Government in many districts and provinces all over India, in previous years never gave them a moment's anxiety. Nor do we find any hint even that the ryots ever thought of compensation or the Government expressed any compunction for refusing to grant licences to cultivate opium. The reason is obvious, the ryots were glad to get rid of it, and the Government knew full well, that crops more remunerative to himself and less troublesome to cultivate, could be selected by the ryots when left free to follow his own choice. But now, when the whole country is seething with discontent, and compensation must be provided for the loss of a very valuable crop, it is not surprising that the Government should have thought of such a thing.

Opium smoking in India.—MR. WILSON has shown that authorities at home are blinded and deceived by the action of the Government of India in these important matters. Two different ministries and two separate Parliaments are shown to have been making the impression that poppy cultivation in India was being considerably reduced: while as a matter of fact, it was very much on the increase.

The China opium trade is the crux of the whole question, and to the views expressed by leading statesmen in China, both Chinese and Europeans, we would now direct attention.

The opinions of Chinese and European Statesmen in China.—As far back as 1816, the traffic in opium between India and China was most emphatically denounced by statesmen whose only interest in opposing the traffic was the protection of an industrious nation from the pernicious influences of the drug. SIR GEORGE STAMFORD STAUNTON, who was in China from 1792 to 1816, said: "The best lands in India might have been made to produce that which was beneficial to man instead of being devoted to the cultivation of such a pernicious article." SIR STAMFORD RUFFLES, who died in 1826, said: "The use of opium, it must be confessed and lamented, has struck deep into the habits, and extended its malignant influence to the morals of the people, (of China) and is likely to perpetuate its power in degrading their character and enervating their energies as long as the European Government over-looking every consideration of policy and humanity shall allow a paltry addition to their finances to outweigh all regard to the ultimate happiness and prosperity of the country." The Colonial Treasurer at Hong-Kong reporting on Chinese trade in 1847, wrote of opium that it was "devastating China, corrupting its Government, and bringing the fabric of that extraordinary empire to a state of more rapid dissolution."

Confucians, Buddhists and Taoists denounce the drug.—The late British Consul in China wrote in 1892 that "opium is equally denounced by the Government, by the Confucian literature, and by the Buddhist and Taoist priesthood."

Chinese Foreign Office and English Statesmen condemn England's Policy.—The Chinese Foreign Office wrote in 1899: "That opium is like a deadly poison that is most pernicious to mankind. The officials and people of this empire all say that England's trade in opium because she desires to work China's ruin, for (say they) if the friendly feelings of England are genuine,—since it is open to her to trade in produce and everything else—would she still insist on spreading the poison of this hurtful thing throughout its empire?" SIR RUTHERFORD ALCOCK, Her Majesty's minister at Peking, with reference to the last quotation, said that "he had no doubt that the abhorrence expressed by the Government and people of China was genuine and deep-seated."

The Royal Commissioners found opium beneficial and legitimate in India. In India on the contrary an enlightened Royal Commission writes of the same drug: "Opium is an absolutely need for non-medical and quasi-medical purposes, to some extent a habit and for the most part a source of serious consequences." That which is a devastat-

ing moral and physical plague in China and the Chinese Settlements is a "benefit" in India? If it cannot be proved that the effects of opium-smoking on the Chinese are widely and essentially different from the effects produced on the natives of India, it is difficult to reconcile the two sets of opinions as referring to the same habit and the same drug.

It becomes a boom in India because Government Revenue is involved.—The only explanation seems to be that in India the officials find it a boom and a blessing because Government revenue is involved, while in China, European Christian, and Chinese officials condemn it because they see and know it to be a degrading habit and a morally devastating curse. There is of course a difference between the smoking of opium and the eating of it, but making due allowance for this, it is notorious that the evils of the habit have been most unblushingly minimised by the official witnesses; while smoking which is universally condemned, is now even fostered, for opium smoking, though universally condemned, is propagated by the lax rules in force in India. There is scarcely one witness of the whole 722 who gave evidence before the Commission who did not decidedly condemn opium-smoking: and with this abundant proof of its deleterious and demoralising effects—amounting to a national curse in China—before us, it is impossible to defend or justify our policy, as a Christian Government, of flooding China and India with this insidious poison.

The traffic unworthy of a great dependency of the British Empire.—In the words of Mr. WILSON "it is altogether unworthy for a great dependency of the British Empire to be thus engaged in a traffic which produces such widespread misery and disaster—a traffic which is contrary to the principles of humanity, cannot be justified on the ground that, if we do not engage in it, it will fall into the hands of others who have no such scruples?"

—10—

SPECIALISM IN MEDICINE.

THERE is certainly more than one side to every question; so while specialism in our profession is cited down by some, it receives staunch support from others. We do not see how specialism, not only in our own, but in any profession, can with any reason be decried. Those who oppose the increase of medical and surgical specialists have yet to discriminate between the would-be and self-constituted repository of special knowledge, and the true devotee to a particular branch of the "healing art" to denounce specialism in medicine in consequence of the tendency of some to rush into its domains from commercial considerations, is as absurd as to denounce orthodox medicine in consequence of existing quacks and quackeries. Some practitioners appear to imagine that a fitting for any particular branch of the profession is sufficient to warrant their ambition to be recognised as specialists in those branches. *The Lancet* and Dr. W. H. SHARRON in the *New York Medical Journal* make some very excellent remarks in considering this subject of specialism in medicine. Says the former, that special knowledge requires special training and special experience, and that a good general medical education is a necessity for one who is to be put and blowed into a special branch of

the profession. Our contemporary remarks that the difficulties in getting on in practice may tempt some to indulge in sharp practices in medicine, but that the idea that all specialism pays is fast disappearing. We expect the same is being played out: and that the numerical growth of so-called specialists makes the public very cautious in the selection of their consultants for special disorders, so that the inferior ones are soon starved out or driven into the ranks of the general practitioners. To enter the roll of specialists without the necessary special training and qualification, but with an imagined aptitude and as a mercenary venture, is one of the most disastrous mistakes that a practitioner can make. One operation unnecessarily undertaken or advised in any one of the very important branches that come under the head of medical specialities is readily brought home to the professional offender, is difficult to be remedied, and is scarcely ever pardoned. Discrimination and varieties in treatment of general diseases is expected, as doctors are known proverbially to differ; but a specialist's failures are more prominently paraded before the public gaze, and are seriously damaging to his own professional career. Even should such a future specialist forsake his special branch and endeavour to establish himself as a general practitioner, he would be looked upon with a certain amount of suspicion as being more of a professional trader than a lover of his calling. We are simply uttering a warning against the temptation of being led into that dangerous assertiveness of proclaiming oneself a consultant in special branches of our profession, without that wide training and experience which the public expects.

Specialism is, however, not only desirable but absolutely necessary, for as Dr. SIMPSON remarks: "Perfection is more readily gained by pursuing one definite line of action;" and instancing the division of the law into civil and criminal practice, and the sub-division of the latter into numerous branches; the division of engineering into civil, mining, and mechanical; the division in mercantile pursuits and in manufactures; the adherence of the artist and the sculptor to special fancies; the special applications in the educational department, &c. Dr. SIMPSON points out that there is a principle of specialism underlying every science and art, a natural division for the cultivation of peculiar fitnesses or bents of mind, and that whatever calling we may pursue in which a certain degree of perfection is to be reached, a proper consideration of and devotion to its special branches is absolutely necessary. Life is too short and scientific advance too rapid, for a human being to stock his brain with all that is known in every branch of his profession; and for individuals to rest content with a smattering only of each and all of its varied sections, means either retrogression or ataxia. It is the special devotion to particular subjects that has so enormously expanded our knowledge of human ailments, and which has led to such specific separation and delimitation of our profession in recent years, into its various sections and branches. In fact, as specialism leads to that research which is ever adding to, correcting, or improving our knowledge in each branch, specialism becomes all the more necessary; in as much as all one can do now-a-days is to obtain anything like a mastery in one medical speciality.

It will be seen from these facts how much we owe to the profession and to our patients in assuming a mastery over any branch of our calling without undergoing a special preparation and training in it. The remarks of *The Lancet* and of Dr. SIMPSON are very apt on this point. Our contemporary enjoins on general practitioners the necessity for inquiring carefully into the reputation for special work of a consultant before sending their patients to him. In so acting, general practitioners can materially suppress any "specialism" abuses which those of mercenary minds may be tempted to practise. And Dr. SIMPSON will have it understood that our patient's welfare claims our first consideration. Prejudice therefore should not, when occasion demands, keep us from sending our patients to proper consultants. Our contention then is, that specialism in our profession, is as much a desideratum as it is in any other. It is more an absolute necessity if we are to advance apace with other branches of science; and no honest practitioner will allow any false pride or petty jealousies to stand between him and his patients' welfare, and prevent him, when he feels his own incompetence in any special case, from referring his patient to the consultant of greatest repute or of well-known efficiency.

COMMENTS AND NEWS.

THE MEDICAL PRACTICE QUESTION IN INDIA.

WE quote from our contemporary on the subject of "official and non-official doctors":—"Our readers may be surprised at the *Indian Planter's Gazette* taking up the subject of medical practice in India, but surprise will give place to the strong conviction that we are well within our sphere of politics, when we lay bare the varied phases of this important matter as it affects our European fellow-subjects in almost every part of this vast Indian Empire. We have been largely led into an earnest consideration of the medical practice question, by reading a series of well-argued and ably written articles that have appeared from time to time in the columns of the *Indian Medical Record*, which during the six years of its prosperous and vigorous existence, has loyally and manfully fought for the cause of independent physicians practising their profession in this land. We have produced quite a number of articles from the *Indian Medical Record* in our own columns from time to time, hoping that a ventilation of the subject would lead to its being properly understood and at the same time serve as a text for such criticism and support as this important public question demands at our hands. With these remarks as a prelude we will try first of all to define the position and work of OFFICIAL AND NON-OFFICIAL DOCTORS in India in general, but more especially in our large cities, and Calcutta in particular. There was a time, over a century ago, when every European doctor in India was a State servant. It is believed that the first independent physician who came to India to set up in practice was a Doctor JOHN C. REDMOND, an Irishman, who settled in the district of Serampore and gained quite a reputation by his skill and good works. Of course as a matter of necessity all the doctoring of European residents up to about fifty years ago, was done by Government doctors, men of the East India Company's service, many of whom amassed huge fortunes, and really deserved their success. During the past thirty years, however, quite a change has been taking over the scene, and the field of medical practice, as it concerns the European and Anglo-Indian community,

which is now patronised by European doctors, for the most part trained in European colleges and universities or a few who have graduated from Indian schools.

Calcutta, Bombay, Madras and Calcutta can boast to-day of as many as three non-official to every single official doctor practising within their limits. It is extraordinary, however, that no change of policy and practice, with regard to the official and private work of Government doctors, has been made during the past fifty or sixty years. This is a most remarkable fact, and it stands out as the only injustice of its kind in the whole of the State Services in India. In no other service, employed and paid by the Government, are its members permitted to perform and to be paid for *private* duties. In fact, such a strange and anomalous privilege is positively denied to men in the Engineering, Public Works, Educational, Judicial and other State-paid departments. What would the Bengal Government say to First Grade Executive Engineer THOMAS MCCARTHY undertaking to design, construct and supervise the erection of the Standard Life Office new buildings during his leisure hours for a certain stipulated fee? Why surely Mr. MCCARTHY would find himself discharged with ignominy from the service of Government. Or suppose that Mr. Chief Secretary WILLIAM JENKINS, C.S.I., who is also a Barrister-at-Law, were to receive clients at his residence after office hours, charging a gold mohur for advice; what would Sir CHARLES ELLIOTT say to such an official? Verily he would conclude that Mr. JENKINS' official work was not enough to keep him fully occupied, and besides warning him that "private enterprise" such as he was indulging in was against Government rules, he would also find *something more* for him to do.

Official doctors are members of the Indian Medical Service who have a covenant to serve in the Indian Army. They hold *military* rank and are styled Lieutenants, Captains, Majors and Lieutenant-Colonels. The higher ranks of Colonels and Generals are forbidden private practice. The word Surgeon is the prefix to the military title in each instance. These officers are ostensibly *military* but they are always employed on civil work. They all hold British diplomas, and are on the whole, fairly well-qualified men. They are allotted to certain State duties as civilians, and they receive handsome monthly salaries for their State work. They have so much leisure time on their hands, that they can earn large fees by extensive private practice.

Non-official doctors have the same diplomas and degrees as their official rivals. They come to this country to make a living by private practice. The majority are excellent men. They should hold the exclusive right to be engaged as family physicians, as medical advisers to mercantile and trading houses, to insurance offices, to railways, port trusts, family pension funds, schools, etc. But traditional usage has rendered the bulk of this vast field of private medical enterprise a huge preserve for official doctors, with whom the emoluments and appointments held by one incumbent pass on to the successor as a sort of hereditary right and title.

Yet Government closes its eyes to this unlawful monopoly and freely permits its paid servants to utilise their leisure hours in "private enterprise," that is, in the remunerative and independent practice of their profession, to the positive detriment of others who are legitimately engaged in private practice and whose bread these Government doctors are most unjustly depriving them of. We say these are facts, and in Calcutta we have them abundantly verified.

It is held that one doctor is sufficient for the medical needs of a community of 1,500 persons, living within a radius of two miles. Granted that the European and Anglo-Indian population of Calcutta is about 10,000, we have over thirty *unaided* independent European physicians practising in the city, or a physician to every thousand of the population.

No one will say Calcutta is fortuitously provided with qualified medical aid for its European community according to such a computation. Yet even with one doctor to every 333 of the population, we find that Government allows its well-paid servants to enter into severe competition with this efficient body of physicians, who are compelled to look to this comparatively small field of private practice alone for their living. Thus a most cruel and unjust rivalry is set up among official and non-official doctors, which is all the more cruelly unjust when it is remembered, that the official doctor is backed by the prestige of a high-sounding military title, by an assured and regular large monthly salary from the Government and by all the conspicuous advantages and privileges that come from being freely and gratuitously advertised in the Government Gazettes and daily periodicals, besides enjoying the monopoly of signing all medical certificates when these are required for even the most obscure State functions. That there is not the smallest justification for official doctors being permitted to engage as general practitioners, on any grounds whatever, we shall abundantly prove in future articles dealing with this subject, and for the present we would ask the earnest attention of our readers to the question of medical practice in India, with the sincere hope that long-standing wrongs and grievances, no matter how deeply rooted and firmly established by precedent or service traditions, shall be abolished in the general interests of the public good.

INDIAN DIPLOMAS FOR SALE.

VERILY those who make laws can break them. Some time back, when BLACKBURN sold diplomas in medicine to certain folk in India and claimed such certificates as holding from JEFFERSON, PA, there was a howl of virtuous indignation, even though the fact remained that the Blackburn papers were sold to those men only who already held junior degrees and had passed all the minor tests of a medical university. Therefore it is with no small surprise that we learn from notification No. 108 of 15th August 1893 and published on page 407 of the *Gazette* for 29th *ibid* that for the small sum of Rs. 50 (less than £3 or \$15) the Punjab Government is prepared to sell the degree of *Bachelor in Medicine* (i.e., M. B.) to any Licentiate of Medicine of two years' standing who can produce certificates (a) of moral and social fitness, (b) of passing in Comparative Anatomy and Physiology and Zoology, and (c) of passing the *Intermediate* examination in Arts. Whether this privilege will be extended to the Military Assistant Surgeons (all of whom have passed the same test required for the L.M.S.) or not, we cannot say, though we might urge that it *ought* to. Yet when we take into consideration the fact that independently of the Arts examination, the standard of education and the test demanded for the M. B., are about six times as hard as those required for the L.M.S., we cannot but conclude that this concession of retrospective elevation, in by no means fair to those M. B.'s who appeared simultaneously for examination with those L. M. S. men to whom this privilege is now extended, and it is more than unfair to the future M.B.'s whose test is considerably raised above that of former years. While it is a decided injustice against the hard worked Assistant Surgeons and Hospital Assistant classes who were educated with these L. M. S. men, and had to pass a *harder* test in *practical* knowledge. Again will not this elevation, on easy conditions of the L. M. S. men *only*, to higher degrees, militate severely against the injustice of not extending the same privilege to those men holding medical titles such as:—O. M. S., C. M. C. C., G. M. C. B., V. L. M. S., D. M. C. C., L. S. A., L. R. C. S., &c. &c., all of which demand a very severe pass, and it must also be remembered that very many of the men holding these diplomas have already passed a higher Arts examination than the "Intermediate"

MILKBORNE DISEASE.

AN APPEAL TO MEDICAL PRACTITIONERS.

MR. ERNEST HART is engaged on a general inquiry, since 1881, on the influence of milk in spreading zymotic disease, and will be much obliged if medical officers, who possess notes of outbreaks of disease traceable to the agency of milk, will be good enough to furnish him with a brief statement of the facts, in the shape of answers to the questions subjoined:—

- | | |
|--------------------------------------------------------|--------------------------------------------------------------------------|
| 1. Date. | 8. Number of milk families involved. |
| 2. Locality. | 9. Sanitary circumstances of farm or dairy from which milk was obtained. |
| 3. Reporter. | 10. Extending cause of outbreak. |
| 4. Total number of cases. | 11. Circumstances implicating milk. |
| 5. Disease. | 12. Facts showing special incidence of disease. |
| 6. Number of cases amongst drinkers of suspected milk. | 13. Reference to report. |
| 7. Number of persons supplied by milkman. | |

THE NEW LIQUOR LAW IN RUSSIA.

WITH a view to diminish drunkenness without reducing the revenue, as well as to regulate the prices of spirits and utterly suppress adulteration and sophistication, the Russian Imperial Government has issued an *ukase* that on and after the 1st July 1898 distilleries, private saloons, bars and liquor shops will be abolished in 8 provinces where the Government will monopolise the manufacture, distribution and sale of spirits. In the July following, the system will be extended to 7 other provinces, and on 1st January 1898 to the remainder of the Russian territories. Suppose India were to follow suit what a deal of good would be done by putting a stop to the import and sale of TONS of vile stuff sold as genuine brandy, whiskey, &c.

THE JUMBLE OF MEDICAL TERMS.

Frequent jumbling up of the macroscopic and typographic significance of terms such as 'descriptive' and 'systematic' as well as the unfortunate grouping together under "one name" of a number of parts that should be *separately* referred to as having separate functions, has so often led to errors in physiological, pathological, medical and surgical parlance and reference, that the *Basic Anatomical Society* appointed a committee to compile a new nomenclature which shall be comprehensive, explicit, rational and more euphonious than the present one, but shall be in Latin, so as to come into universal use. Such a work is urgently needed.

SHORT ITEMS.

It has been ruled that when a Brigade Surgeon Lieutenant-Colonel of the I. M. S. is attached to the office of the P. M. O. to learn military medical administration, without relinquishing his civil duties, he will draw full civil pay, but if he is obliged to give up his civil appointment, he will draw the grade pay of his rank together with half of the difference between his grade pay and the substantive salary of his civil appointment.

An unregistered chemist's assistant, giving evidence at an inquest at Limehouse, stated that he had attended the sick and dying and bereaved in ten districts of London during the past six years, and that he lived only to do good to others. The Coroner gave him some useful and temperate advice, together with a wholesome dressing down that ought to do him a world of good to set upon the doctor's place.

In the list published of those who attended the annual meeting of the British Medical Association and listened to Dr. Ernest Hart's *generous* address (page 201) we are glad to notice the names of several Anglo-Indians and Europeans, who have settled down in Europe; but we are more pleased to find that some, who attended, went direct from India, where they have laid their "stone of life."

Dr. Dave of Calcutta (the late Dr. Dave) had removed from the nose of a woman, aged 35, who had consulted him for ear trouble. The tooth which was a small canine had for 50 years been growing in a small depression at the junction of the floor and external wall of the nasal cavity, 0.9 inch from the external nares and was easily extricated.

The quarterly report of the Pasteur Institute shows that from January to March, instant, 845 persons were treated and 844 recovered, while the one who died caught cold by riding on the outside seat of an omnibus, after taking a hot bath. Of the animals that inflicted the bites 321 were dogs, 15 cats and 1 ass.

I. V. R. C. in the *British Medical Journal* suggests the perpetration of another jobbery for the Indian Medical Service in the appointment of a Sanitary Member of the Council of the Secretary of State for India. Of course he must be an I. M. S. man.

From Rajpattan, *India* writes to the *British Medical Journal* complaining that the Church Missionary Society is trying to starve out the local medical practitioners by bringing out two doctors who treat *gratis* every one who attends their dispensary or calls them out.

Norway and Sweden do things with a high hand, as the legislature rules that no couple can be legally married unless they can produce certificates proving that both the man and the woman have been satisfactorily vaccinated.

Mrs. Sarah Tattle of Hartford, Conn., has bequeathed \$29,000 to the following charities:—Old people's home, 10,000; Hartford Hospital, 5,000; Orphan Asylum, 5,000; Larrabee Fund, 6,000; Home Work Union, 2,000; and Church Home 1,000.

Bankipore society is anxious for Government to confirm Dr. Davill as local Civil Surgeon, as he is extremely popular with the European community, and is much liked by all the natives.

Dr. Ernest Hart fairly demolishes Dr. A. Crombie's address to the Calcutta Medical Society, which he characterises as calculated to do a great amount of harm; for it is mixed up with many errors of fact.

Calcutta might well learn a lesson from Paris where the Prefect of police has given strict orders to his inspectors to investigate the causes and sources of the disagreeable smells which regale the Parisian nostrils of an evening.

We regret to announce the death on 20th August, at the age of 68, of Professor J. S. Bristowe, F.R.S., the well-known author of "Bristowe's Practice of Medicine."

The University of Edinburgh has conferred the degree of LL.D. on Dr. S. Weir Mitchell of Philadelphia, who is now a double LL.D.

Four Eurasians are among the successful competitors for the I. M. S. in the list published in this issue.

Members of the Indian Medical Association, who have not paid their subscriptions, will oblige the Treasurer (Surgeon-Major H. C. Hodgkins, B.A.S., Medical College, Calcutta) by sending them in without delay.

Subscribers in arrears with their payments to the "Indian Medical Record" will oblige the Treasurer by remitting their dues as early as possible.

MILKBORE DISEASE.

AN APPEAL TO MEDICAL PRACTITIONERS.

MR. BENNET HAAS is engaged on a general inquiry, since 1881, on the influence of milk in spreading zymotic disease, and will be much obliged if medical officers, who possess notes of outbreaks of disease traceable to the agency of milk, will be good enough to furnish him with a brief statement of the facts, in the shape of answers to the questions subjoined:—

1. Date.
2. Locality.
3. Reporter.
4. Total number of cases.
5. Details.
6. Number of cases amongst drinkers of suspected milk.
7. Number of persons supplied by milkman.
8. Number of such families involved.
9. Sanitary circumstances of farm or dairy from which milk was obtained.
10. Exciting cause of outbreak.
11. Circumstances implicating milk.
12. Facts showing special incidence of disease.
13. Reference to report.

THE NEW LIQUOR LAW IN RUSSIA.

WITH a view to diminish drunkenness without reducing the revenue, as well as to regulate the prices of spirits and utterly suppress adulteration and sophistication, the Russian Imperial Government has issued an *ukase* that on and after the 1st July 1896 distilleries, private saloons, bars and liquor shops will be abolished in 8 provinces where the Government will monopolise the manufacture, distribution and sale of spirits. In the July following, the system will be extended to 7 other provinces, and on 1st January 1898 to the remainder of the Russian territories. Suppose India were to follow suit what a deal of good would be done by putting a stop to the import and sale of TONS of vile stuff sold as genuine brandy, whisky, &c.

THE JUMBLE OF MEDICAL TERMS.

Frequent jumbling up of the macroscopic and typographic significance of terms such as 'descriptive' and 'systematic' as well as the unfortunate grouping together under "one name" of a number of parts that should be *separately* referred to as having separate functions, has so often led to errors in physiological, pathological, medical and surgical parlance and reference, that the *British Anatomical Society* appointed a committee to compile a new nomenclature which shall be comprehensive, explicit, rational and more euphonious than the present one, but shall be in Latin, so as to come into universal use. Such a work is urgently needed.

SHORT ITEMS.

It has been ruled that when a Brigade Surgeon Lieutenant-Colonel of the I. M. S. is attached to the office of the P. M. O. to learn military medical administration, without relinquishing his civil duties, he will draw *full* civil pay, but if he is obliged to give up his civil appointment, he will draw the grade pay of his rank together with half of the difference between his grade pay and the substantive salary of his civil appointment.

An unregistered chemist's assistant, giving evidence at an inquest at Limehouse, stated that he had attended the sick and dying and bereaved in ten districts of London during the past six years, and that he lived only to do good to others. The Coroner gave him some useful and temperate advice, together with a wholesome dressing down that ought to do him a world of good to not usurp the doctor's place.

In the list published of those who attended the annual meeting of the British Medical Association and listened to Dr. Ernest Hart's *powerful* address (page 261) we are glad to notice the names of several Anglo-Indians and Europeans, who have settled down in Europe; but we are more pleased to find that some, who attended, went direct from India, where they have laid their "bones of life."

Dr. Dave of Calcutta (Ganges) *discovered* a *cat* had *remained* from the nose of a woman, aged 35, who had consulted him for ear trouble. The tooth which was a *cat* canine had for 40 years been growing in a small depression at the junction of the floor and external wall of the nasal cavity, 0.9 inch from the external nares and was easily extracted.

The quarterly report of the Pasteur Institute shows that from January to March, instant, 845 persons were treated and 844 recovered, while the one who died caught cold by riding on the *outside* seat of an omnibus, after taking a hot bath. Of the animals that inflicted the bites 324 were dogs, 15 cats and 1 ass.

I. V. R. C. in the *British Medical Journal* suggests the perpetration of another jobbery for the Indian Medical Service in the appointment of a Sanitary Member of the Council of the Secretary of State for India. Of course he must be an I. M. S. man.

From Rajputana, *India* writes to the *British Medical Journal* complaining that the Church Missionary Society is trying to starve out the local medical practitioners by bringing out two doctors who treat *gratis* every one who attends their dispensary or calls them out.

Norway and Sweden do things with a high hand, as the legislature rules that no couple can be legally married unless they can produce certificates proving that both the man and the woman have been satisfactorily vaccinated.

Mrs. Sarah Tattle of Hartford, Conn. has bequeathed \$29,000 to the following charities:—Old people's home, 10,000; Hartford Hospital, 5,000; Orphan Asylum, 5,000; Larrabee Fund 6,000; Home Work Union, 2,000; and Church Home 1,000.

Banikpore society is anxious for Government to confirm Dr. Bovill as local Civil Surgeon, as he is extremely popular with the European community, and is much liked by all the natives.

Dr. Ernest Hart fairly demolishes Dr. A. Grombie's address to the Calcutta Medical Society, which he characterises as calculated to do a great amount of harm; for it is mixed up with many errors of fact.

Calcutta might well learn a lesson from Paris where the Prefect of police has given strict orders to his inspectors to investigate the causes and sources of the disagreeable smells which regale the Parisian nostrils of an evening.

We regret to announce the death on 20th August, at the age of 68, of Professor J. S. Bristowe, F.R.S., the well-known author of "Bristowe's Practice of Medicine."

The University of Edinburgh has conferred the degree of LL.D. on Dr. S. Weir Mitchell of Philadelphia, who is now a *double* LL.D.

Four Eurasians are among the successful competitors for the I. M. S. in the list published in this issue.

Members of the Indian Medical Association, who have not paid their subscriptions, will oblige the Treasurer (Surgeon-Major E. O. Hodgkins, M.A.S., Medical College, Calcutta) by sending them in without delay.

Subscribers in arrears with their payments to the "Indian Medical Record" will oblige the Proprietor by remitting their dues as early as possible.

OUR LONDON LETTER.

(From our own Correspondent.)

Among items of medical interest lately to the fore and the very first of its kind is a curious deformity in a newly-born babe in whom arrested development of the skull left the brain so unprotected that it threatened to fall out every time the child was moved about.

The Empire of India Exhibition which, is being held in the extensive grounds at Earl's Court, is of a polyglot nature.

There is a representation of an Indian street with shops peopled by native artisans, performing their various duties as silver and goldsmiths, carpet and cotton weavers, printers, potters, and glassblowers. There are a series of

pictures painted in India with samples of ivory carving, Masulipatam and Benares work, Sanskrit M. S. S. of ancient date, &c. Burma has its section with its dancing girls and characteristic music. Indian jugglers perform their feats. There is also an Indian menagerie and lady snake-charmer; and lastly there is a graphic representation of a jungle, by night, with stuffed figures of birds, animals and reptiles in various predatory attitudes.

Cases of abortion are more rife than ever, only a short time back the body of a lady, Mrs. L. SCOTT CAMPBELL, was exhumed at Kensal Green, the post-mortem proving that operative measures had produced miscarriage and death. Dr. W. M. COLLINS has been implicated, but to what extent is yet unknown.

The M. B. watch, manufactured especially for the use of medical men, in all countries, is a unique production.

report of the Board of Health of New York, that in one hundred and eighty-six cases of so-called membranous croup, eighty per cent. showed the signs of true diphtheria, fourteen per cent. showed those of pseudo-diphtheria, and six per cent. were doubtful. To true croup the attack is usually insidious. The voice at first becomes gradually lost. The cough, at first metallic, soon becomes smothered. Attacks of dyspnoea begin at long intervals, but the intervals soon become shorter and irrespective of day or night. All the signs are progressive in character. The diagnosis should be made, if possible, by bacterial examination. The larynx should only be applied to a pathologist's microscope as a warning of the culture of the larynx from the deposits of exudation or false membrane upon its mucous surface. It is true in diphtheria in such a large proportion of cases that every case should be regarded as one of diphtheria, unless definitely proved to be something else.—*Med. Rec.*

Surgeon-Captain Whitechurch has been adjudged the V. C. for distinguished bravery in the Chitral Campaign. Surgeon General CHARLES R. FRANCIS, M.D., London, M.R.C.P., late Principal and Professor of Medicine in the Calcutta Medical College, reports a case of an officer (after 30 years Indian service and *ætat.* 74) suffering from four distinct attacks of influenza and attributes his relapses, at least, to the situation of the patient's house on a damp soil. A painless way of treating hydrocele has been talked of by first draining off some of the fluid, then injecting 3i of a 1 per cent cocaine solution, finally evacuating the serum entirely and then injecting tincture of iodine. M. L. VILLARD, since he finds acute tetanus is difficult to cure, advises prophylaxis by rendering animals and men previously immune to the tetanic poison, and this can with certainty, he reports, be effected by injections of carefully prepared anti-tetanic serum.

Current Medical Literature.

MEDICINE.

What is Croup.

IN an article under this title DR. HENRY DESSAU, attempts to define the exact meaning of the term croup. Several disorders which vary widely in the nature are called croup. Laryngismus stridulus and catarrhal laryngitis are the commonest of these. The first is practically a manifestation of rickets and is in no sense croup. It often appears as the holding-breath spell of rickety infants in which the face becomes livid, with perhaps convulsive twitching of the muscles of the face, followed by a loud crowing expiration. Catarrhal laryngitis, or false croup, appears in two forms, the spasmodic and the simple. The spasmodic comes on suddenly at night, awaking the child out of sleep and rarely occurs in children under a year old. Its most prominent features are a loud metallic ringing quality of the cough and alarming dyspnoea. The simple form of laryngitis develops gradually with hoarseness and a ringing tone of the cough. It may begin during the day, but becomes more marked at night. There is usually elevation of temperature, and frequently there are attacks of difficult breathing. The voice is never completely lost. It is very difficult to distinguish the form of laryngitis from true diphtheria. When the signs of diphtheria or pseudo-diphtheria have been recognized after such a laryngitis, the case presents great difficulties in diagnosis. According to a recent

report of the Board of Health of New York, that in one hundred and eighty-six cases of so-called membranous croup, eighty per cent. showed the signs of true diphtheria, fourteen per cent. showed those of pseudo-diphtheria, and six per cent. were doubtful. To true croup the attack is usually insidious. The voice at first becomes gradually lost. The cough, at first metallic, soon becomes smothered. Attacks of dyspnoea begin at long intervals, but the intervals soon become shorter and irrespective of day or night. All the signs are progressive in character. The diagnosis should be made, if possible, by bacterial examination. The larynx should only be applied to a pathologist's microscope as a warning of the culture of the larynx from the deposits of exudation or false membrane upon its mucous surface. It is true in diphtheria in such a large proportion of cases that every case should be regarded as one of diphtheria, unless definitely proved to be something else.—*Med. Rec.*

Traumatic Glycosuria.

DR. F. A. HIGGINS and DR. J. B. OGDEN (*Bacter. Medical and Surgical Journal*) remark that in addition to permanent glycosuria following traumatism of the head there is another form mentioned by some observers, and of which a number of cases have been reported. This last form is mostly transitory, and comes on directly after the traumatism or in a few days. On the other hand, the permanent form of glycosuria occurs at a period of weeks or even months afterwards. After giving an account of the various changes of cases met with they summarise their conclusions as follows: 1. That, after injury, sugar may appear in the urine as early as six hours and disappear within twenty-four, the average time for its appearance, however, being from eight to twelve hours; and for the disappearance of the same from the fifth to the ninth day. 2. That a small proportion of the cases may exhibit a permanent glycosuria from the date of injury to the head. 3. That acetone and diacetic acid are rarely, if ever, found in such cases, excepting where the condition becomes a permanent glycosuria, and even then probably only after a number of months or years. 4. That of the twenty sugar cases recorded in the paper, eleven (55 per cent.) had received an injury to the right side of the head, five (25 per cent.) to the left side, three (15 per cent.) to the occiput, and two (10 per cent.) where there was no external evidence of violence. 5. That it is impossible in the present state of the knowledge of the pathology of diabetes and glycosuria to draw any inferences from the necropsies which have been obtained. They are, however, reported in full. 6. There is little to be said in regard to the mortality. Of the twenty cases eight died, six being the direct result of severe injuries, one from intercurrent disease, and one from the probable effects of alcoholism. In the 119 cases sixteen were fatal, 50 per cent., of these having glycosuria. Albumen, together with casts and abnormal blood, was found in every case containing sugar, probably secondary in most instances to the renal irritation produced by the sugar, even though it had been eliminated only a short time.

Neuroses of Childhood.

DR. B. K. RACHFORD after a careful and prolonged study of the effect of a venous condition of the blood in producing neurotic diseases in children, draws the following conclusions:—

1. Both arterial anæmia and venous congestion can excite the nervous system and may therefore be factors in the producing of nervous symptoms.
2. The nervous symptoms resulting from arterial anæmia are very similar to those resulting from venous congestion,

Dr. H. J. HARRIS and HARRISON, respectively, for the effects of epinephrine came from the University of Cambridge. Dr. HARRISON, who is a dangerous infection which frequently suffers from acute septicaemia. Dr. HARRIS reports a case of double urethra, and this is unique in the history of medical science. The remedy against insanitary bakeries is at length showing signs of achieving success in its practical and humane mission. DR. RICHARD THORNE THORNE, C.B., F.R.S., succeeds SIR JOHN SIMON as a member of the General Medical Council. SIR PETER EAPEN, M.D., has for the first time been elected Mayor of Norwich. At the last meeting of the General Council there was a long discussion on the revision of the British pharmacopoeia. The Therapeutic Committee of the British Medical Association has submitted a useful memorandum to the Council.

Surgeon-Captain Whitechurch has been adjudged the V. C. for distinguished bravery in the Chitral Campaign. Surgeon General CHARLES R. FRANCIS, M.B., London, M.R.C.P., late Principal and Professor of Medicine in the Calcutta Medical College, reports a case of an officer (after 30 years Indian service and *et al.* 74) suffering from four distinct attacks of influenza and attributes his relapses, at least, to the situation of the patient's house on a damp soil. A painless way of treating hydrocele has been talked of by first draining off some of the fluid, then injecting 3i of a 1 per cent cocaine solution, finally evacuating the serum entirely and then injecting tincture of iodine. M. L. VILLARD, since he finds acute tetanus is difficult to cure, advises prophylaxis by rendering animals and men previously immune to the tetanic poison, and this can with certainty, he reports, be effected by injections of carefully prepared anti-tetanic serum.

MEDICINE.

What is Croup.

IN an article under this title DR. HENRY DESSAU, attempts to define the exact meaning of the term croup. Several disorders which vary widely in their nature are called croup. Laryngismus stridulus and catarrhal laryngitis are the commonest of these. The first is practically a manifestation of rickets and is in no sense croup. It often appears as the holding-breath spell of rickety infants in which the face becomes livid, with perhaps convulsive twitching of the muscles of the face, followed by a loud crowing inspiration. Catarrhal laryngitis, or false croup, appears in two forms, the spasmodic and the simple. The spasmodic comes on suddenly at night, awaking the child out of sleep and rarely occurs in children under a year old. Its most prominent features are a loud metallic ringing quality of the cough and alarming dyspnoea. The simple form of laryngitis develops gradually with hoarseness and a ringing tone of the cough. It may begin during the day, but becomes most distressing at night. There is usually elevation of temperature, and frequently there are attacks of difficult breathing. The voice is never completely lost. It is very difficult to distinguish the form of laryngitis from whooping cough. When the signs of diphtheria or pseudo-diphtheria have been suggested after such a laryngitis, the case presents great difficulties in diagnosis. According to a recent

report of the Royal Society of Medicine, the 1000 children and slightly above the mean of several thousands, during slightly per cent showed the signs of true diphtheria, fourteen per cent showed those of pseudo-diphtheria, and six per cent were doubtful. In true croup the onset is usually insidious. The voice at first becomes gradually lost. The cough, at first rattling, soon becomes smothered. Attacks of dyspnoea begin at long intervals but the intervals soon become shorter and irrespective of day or night. All the signs are progressive in character. The diagnosis should be made, if possible, by bacterial examination. The term croup should only be applied to a pathological condition of narrowing of the calibre of the larynx from the deposit of a membrane or false membrane upon its mucous surface. It is due to diphtheria in such a large proportion of cases that every case should be regarded as one of diphtheria unless definitely proved to be something else.—*Med. Rec.*

Traumatic Glycosuria.

DR. F. A. HIGGINS and DR. J. B. OGDEN (*British Medical and Surgical Journal*) remark that in addition to permanent glycosuria following traumatism of the head there is another form mentioned by some observers, and of which a number of cases have been reported. This last form is usually transitory, and comes on directly after the traumatism or in a few days. On the other hand, the permanent form of glycosuria occurs at a period of weeks or even months afterwards. After giving an account of the various changes of cases met with they summarise their conclusions as follows: 1. That, after injury, sugar may appear in the urine as early as six hours and disappear within twenty-four, the average time for its appearance, however, being from eight to twelve hours; and for the disappearance of the same from the fifth to the sixth day. 2. That a small proportion of the cases may exhibit a permanent glycosuria from the date of injury to the head. 3. That acetone and diacetic acid are rarely, if ever, found in such cases, excepting where the condition becomes a permanent glycosuria, and even then probably only after a number of months or years. 4. That of the twenty sugar cases recorded in the paper, eleven (55 per cent.) had received an injury to the right side of the head, five (25 per cent.) to the left side, three (15 per cent.) to the occiput, and two (10 per cent.) where there was no external evidence of violence. 5. That it is impossible in the present state of the knowledge of the pathology of diabetes and glycosuria to draw any inference from the necropsies which have been obtained. They are, however, reported in full. 6. There is little to be said in regard to the mortality. Of the twenty cases eight died, six being the direct result of severe injuries, one from intercurrent disease, and one from the probable effects of alcoholism. In the 119 cases sixteen were fatal, 50 per cent. of those having glycosuria. Albumen, together with casts and abnormal blood, was found in every case containing sugar, probably secondary in most instances to the renal irritation produced by the sugar, even though it had been eliminated only a short time.

Neuroses of Childhood.

DR. B. K. RACHFORD after a careful and prolonged study of the effect of a venous condition of the blood in producing neurotic diseases in children, draws the following conclusions:—

1. Both arterial anaemia and venous congestion can excite the nervous system and may therefore be factors in the producing of nervous symptoms.
2. The nervous symptoms resulting from arterial anaemia are very similar to those resulting from venous congestion,

and this is because in both conditions there is a venous condition of the blood supplying the nerve centers.

3. Arterial anæmia and venous congestion produce nervous symptoms by producing a malnutrition rather than a simple inanition of the nerve centers.

4. Arterial anæmia and venous congestion weaken the inhibitory centers, and this results in the discharge of force from reflex centers on comparatively slight excitation.

5. Arterial anæmia and venous congestion make more excitable both the reflex centers in the cord, and the more important reflex centers in the medulla oblongata.

The following examples may be cited to indicate the important relationship existing between a venous condition of the blood and the neuroses of childhood.

1. The nervous condition of the blood resulting from a weak or crippled heart, is partially explanatory of the relationship existing between this condition of the heart and certain neuroses such as cholera, hysteria and general nervous irritability.

2. Rheumatism, scarlet fever, diphtheria and other acute diseases which oftentimes produce a weakened condition of the heart, may in this way be indirect factors of neurotic disease.

3. Tuberculosis, chronic intestinal catarrh and other diseases that produce a profound chronic anæmia and resulting malnutrition of the nervous centers may be powerful factors in producing many of the neuroses, such for example as hysteria, incontinence of urine, chorea and spasm.—*Gaillard's Med. Journ.*

Syphilis and Tabes Dorsalis.

THERE are many opinions as to the role played by syphilis in different diseases; one of these is locomotor ataxy, an affection that we believe some physicians look upon as entirely due to this one cause. CARDARELLI believes the importance of syphilis as a cause of tabes dorsalis to be greatly exaggerated, but says that possibly one-third of the cases of ataxy may be of syphilitic origin. When the disease appears twenty or thirty years after the primary chancre, and is not preceded by any decided specific manifestation during this time, he does not believe it to have any casual relationship to the syphilis. Of course, whether this is the case or not, the question has an important influence on treatment. CARDARELLI points out that anti-syphilitic remedies, as a rule, do more harm than good, and says that in any case in which this form of treatment does no good in fifteen to twenty days, it is useless to persevere with it. May not, however, this failure of specific treatment be due to other causes? It must be remembered that the ways of tertiary syphilis are peculiar, and we would point out particularly that the inflammatory exudation, which is a characteristic of that stage, is not long in transforming itself into fibrous tissue, so that, unless taken early, specific drugs cannot be of much avail. Perhaps, could we be sure of getting tabes dorsalis at a very early stage—or, for the matter of that, cases of carcinoma, sarcoma, and other diseases, and were consequently at once able to apply appropriate treatments—our results would shew a decided improvement, and fewer cases would be pronounced incurable.—*Med. Jour. and Hosp. Gazette.*

Hereditary Syphilis in the Second Generation.

GEORGE EITNER recounts the history of a family in the service of Professor BRILMAN in the Nancy Hospital. The paternal grand mother died at the age of fifty-five of syphilitic caries of the os maxilla. The father of the family in question was attacked when thirty-four years of age by an aphasia, which was rapidly cured by mercurial inunctions. He suffered continually from epistaxis, and

was killed by fall from his horse in his thirty-seventh year. The autopsy disclosed no other specific lesions.

In the second generation the statistics of fifteen pregnancies were five abortions; a child of early development, who began to speak at eight years of age; five children afflicted with mental disturbances or with persistent cephalalgia, always ameliorated by antisyphilitic treatment; one daughter who died of suspicious alarvative accident; another girl born in a state of semimacération, attacked later by a painless ulceration of the palatal wall and by an eruption which left linear white cicatrices; lastly, defective dental formation, which this last child shared with one of her sisters. The abortions did not follow the classic type in syphilis. The first was preceded by a normal pregnancy, and it was only much later (pregnancies 7, 9, 12, and 14) that they became frequent. At the same time, however, they coincided largely with the tardy outbreaks in the father, the seventh child being carried at the time of his aphasic attack, and the accidents becoming more serious and more characteristic hereafter.—*N. Y. Med. Rec.*

A Constant Sign of Commencing Meningitis.

THIS consists in the inharmonious movements of the chest and diaphragm. It exists from the beginning, and may serve to reveal its cause even in insidious cases, but requires careful searching. The chest and abdomen must be bared, but not suddenly, or the hyperæsthetic skin will take on accidental movements from the action of the air.

In the first period of meningitis may be seen irregularity of rhythm and inequality of the amplitude or development of the chest. Another sign is the irregular type of respiration and dissonation of the movements of chest and diaphragm. The respiration is effected by the lower respiratory muscles of the chest. Looking at the umbilical region, instead of the normal elevation with each inspiration, there is either immobility or depression. These movements are not connected with the Cheyne-Stokes type of respiration.—*Times and Register.*

Eye-Strain a Cause of Nocturnal Enuresis.

DR. GEO. M. GOULD reports a number of cases of children who were afflicted with nocturnal enuresis, accompanied by many other nervous symptoms, such as night terrors, headaches, chorea, etc., nearly all of which were also relieved or cured by wearing glasses that corrected the visual anomaly. Some of the patients had undergone operation and treatment that had extended over years without relief of the trouble.—*Medical News.*

SURGERY.

Anchoring the Kidney.

GREATER skill and care in diagnosis has led to the discovery, in recent years, of many cases of movable or floating kidneys. Many patients, therefore, who formerly suffered for months or years from pains, or at least considerable discomfort, in the side, together with, in due course, the formation of degenerative or cystic disease of the kidney, are now speedily relieved or cured. Moreover, it has become recognized that the displacement of the organ is by no means the harmless occurrence which it was formerly considered to be. The twisting of the ureter, necessarily following the displacement of the kidney, leads first to blocking of the duct and then to degenerative changes in the calyces of the organ from pressure of the retained urine. As a clinical fact it is worth remembering that it is more usual to find a movable kidney on the right side than on the left, because the former is, as a rule, located rather lower than the opposite organ.

The operation which has been suggested in America for "anchoring" a flapping or movable kidney, consists in making the ordinary perpendicular incision over the median line of the kidney, usually from two-and-a-half to three inches in length. The incision having been made sufficiently large to permit the introduction of the fingers, the kidney is brought back to its normal position, a needle is inserted through the upper and inner part of the cortical substance of the organ and then through the muscles of the back, and out through the skin on each side, the peritoneal surfaces being scarified so as to favor the formation of adhesions. A second needle is passed about an inch from the other through the upper and inner part of the kidney and out through the muscles and integument, and the sutures are then tied outside on the skin. In tying them it should be remembered that they must be drawn sufficiently tight not only to hold the organ in place, but also to produce sufficient irritation to excite inflammatory adhesions, and yet not so tight as to tear through the substance of the kidney. The rest of the abdominal wound is then closed in the ordinary manner, and the sutures are left in place for ten days or a fortnight. It is claimed that the operation is not only simple and rapid, practically bloodless and safe, but that its results are excellent.—*Med. Times and Hosp. Gaz.*

Rules for Trephining in Injury of the Skull.

1. ALL cases of depressed fracture, either simple or compound, require trephining and elevation, whether there be pressure symptoms or not.
2. All punctured fractures and gunshot wounds imperatively indicate the use of the trephine.
3. In simple fracture of the skull, where any symptoms of brain trouble persist, exploratory operation should be done.
4. In all cases of local injury to the skull, whether fracture or bruise, followed by evidence of inflammation of bone or persistent symptoms of brain irritation, or of pus between the bone and dura, the trephine should be resorted to.
5. In every case of localized injury to the head where unconsciousness persists for more than an hour, exploratory operation, including opening the skull if necessary, should be done.
6. The appearance of stupor some hours after a head injury indicates meningeal hemorrhage and requires trephining at the point of injury, if known, or at point indicated by cerebral localisation, the middle meningeal being the usual source of trouble.
7. Even in very extensive injury to the head operation should be made since removal of fragments, restoration of normal contour and cleaning of injured tissues can add but little to the danger and may save life.
8. In every case of doubt exploratory operation is justifiable.
9. Compound fractures, with or without apparent depression, demand enlargement of the wound and careful exploration.—*St. Louis Clinique.*

First Aid to Persons Injured by Electric Currents.

PROFESSOR GAZIEL, presents the following as his conclusions:—

When a person meets with an accident due to contact with electric conductors or generators, the contact must first be broken. If it still exists, as otherwise those who come to render assistance may also become victims of the same accident;

The victim is to be carried to a well-ventilated room, from which all persons except, at the most, three or four assistants, are excluded;

The clothing should be loosened at once, and efforts are to be made at the earliest possible moment to re-establish respiration and circulation.

Lastly:—

To restore respiration, recourse should be had mainly to the following two procedures: Rhythmical traction on the tongue and artificial respiration; but both must be continued for a sufficiently long time:

Lastly, concurrently with these procedures, the circulation should be stimulated by rubbing of the skin, flagellation of the trunk with the hand or wet towels, and any other means usually resorted to in such cases:—*Amer. Med. Surg. Bull.*

The Hygiene of the Eyes.

For the preservation of the eye-sight Dr. L. W. FOX, Professor of Ophthalmology, Medico-Chirurgical College, Philadelphia advises us:—

- (1) Avoid sudden changes from dark to brilliant light, stimulants and drugs affecting the nervous system, and reading when lying down, or when mentally and physically exhausted.
- (2) When the eyes feel tired, rest them by looking at objects at a long distance.
- (3) Pay special attention to the hygiene of the body, for what tends to promote the general health benefits the eye.
- (4) Up to forty years of age, bathe the eyes twice daily in cold water; but after fifty, bathe them morning and evening with water as hot as you can stand; follow this with cold water, this will make them glow with warmth.
- (5) Old persons should avoid reading much by artificial light, be guarded as to diet, avoid sitting up late at night and not depend on their own judgment in selecting spectacles.
- (6) Do not give up in despair when informed that cataract is developing: in these days of advancing surgery it can be removed with little danger to the vision.

Congenital Absence of the Entire Tibia.

JOACHIMSTHAL reports the following case:—A little girl, one and a half year old, came to Professor WOLFF's clinic. The right tibia was entirely absent, the foot in a marked position of varus, and the fibula, which was the only bone present in the leg, did not articulate with the femur, but could be felt behind it. The condyles of the femur were very prominent, and the patella could be felt in the inter-condylar notch. The fibula was two and a half centimetres shorter than its fellow, and much thicker. The right buttock was somewhat smaller than the left. The leg was flexed on the thigh. WOLFF corrected the varus after tenotomy of the ten to Achilles. By means of a long incision, free access was gained to the knee-joint. There were no semilunar cartilages nor crucial ligaments. The head of the fibula was pulled down until it rested between the condyles of the femur, no section being taken from it in order to avoid still further shortening the leg. The capsule was then stitched. As the leg could be completely extended on the thigh after the operation, it was put up in a slightly flexed position in a plaster of Paris bandage, which at the same time retained the foot in good position.—(*Arch. de Orthoped.—Hospital*)

Supra-pubic Cystotomy for Calculus.

DR. A. H. MEISENBACH sums up a paper on this subject with the following conclusions: 1. That the transverse incision is more easily executed from an oblique standpoint. 2. That it affords more space in which to work in the depths

of the wound than the median incision, and seems to be superior to any exploration of the bladder, for whatever condition. 2. That there is less liability to injury of the peritoneum, because the incision is parallel with and on a level below its lowest fold. 3. That it is unnecessary to inflate the rectum. 4. That it is unnecessary to inject the bladder, and consequently this risk of injury to the organ is avoided, which in the aged is an element that should always be considered. 5. That the catheter in the bladder is a safe guide to the location of the fundus and anterior wall. 7. That with the catheter as a guide, the bladder can be incised with ease and facility.—*Jour. Amer. Med. Assoc.*

A New Method of Cholecystotomy.

BLOCK describes a new method of performing cholecystotomy with a view to avoiding peritonitis, and the formation of firm adhesions between the gall-bladder and the abdominal wall after the establishment of a temporary fistula. In the method called extra-abdominal cholecystotomy, which was successfully practised by him the distended gall-bladder is drawn through the abdominal wound, (and a portion about the size of a hen's egg outside this wound) by sutures, until adhesions have formed and the peritoneal cavity has been closed. The gall-bladder is then opened, the gall-stones, if any contain, are removed, and the wound, in its coats, having been closed by sutures, the gall-bladder, after a further interval to allow of complete cicatrization, is separated from the margins of the incision in the abdominal wall and returned into the peritoneal cavity when the external wound is finally closed.

OBSTETRICS AND GYNECOLOGY.

Uterine Gonorrhoea.

WETHEIM believes that next to the urethra the uterus is the most common seat of gonorrhoea. The germ sets up true acute interstitial endometritis; in chronic disease the glandular tissue of the endometrium is greatly increased. The muscular coat is often involved, and a kind of sclerosis of the vessels occurs, whilst the connective tissue undergoes hyperplasia at the cost of the muscle cells. Gonoecocci are usually to be found in the inflamed mucosa, yet sometimes they are entirely absent, and they rarely, if ever, can be detected in the exudations in the muscular coat. The os internum offers no protection to the entrance of gonorrhoeal poison into the uterine cavity. The cervix is less involved, and the disease is always least marked nearest the os externum. The puerperium is the most dangerous condition when gonorrhoea exists in the genital tract lower than the uterus. Menstruation, coitus, and the sound are much less liable to expose the uterine cavity to gonorrhoeal infection.—*R. M. J.*

Pregnancy with Imperforate Hymen.

BRAYN was consulted by a newly-married woman who had found herself unfit for complete cohabitation. He examined and found a vaginal appearance of the external parts, a tight and narrow hymen, and pregnancy advanced to the fifth month. The patient had a generally contracted funduliform pelvis, and caesarean was needed at the end of pregnancy. BRAYN notes that penetration must have been impossible in this case, where pregnancy occurred before the patient suspected it.—*R. M. J.*

Thirst Following Abdominal Section.

In the column of the paper read by Dr. HUGHES BORTH, at Royal Society, before the Anatomical Society,

logical and Obstetrical Societies, for abstracting water from the abdominal vessels, that the sensation of thirst is caused by the withdrawal of water from the vessels in the veins depleted by excessive perspiration, thirst following abdominal section is caused by the withdrawal of water from the abdominal vessels to fill veins partially collapsed by reason of diminished blood supply, because of contraction of the arteries of the viscera. The sensation invariably follows the withdrawal of any considerable amount of fluid from the body; the withdrawal of such fluid causes proportionate collapse of veins and capillaries. Capillaries tend to remain at normal tension, and when suddenly collapsed in any degree attempt to regain that tension by taking water from the surrounding tissues. Irritation of sympathetic nerves causes contraction of the arterioles supplied by such nerves. Sudden contraction of the arterioles supplying any organ is followed by lessened tension in the capillaries and small veins of that organ. Abdominal section invariably causes direct and reflex irritation of the abdominal sympathetic nerves. Such irritation causes contraction, in some degree, of the arterioles of the abdominal viscera, with consequent lessened tension in their capillaries, and compensatory withdrawal of water from their tissues.

In this connection the practice of some of the modern gynecologists is interesting. A pint of water, at blood heat, is injected into the rectum, and this is repeated every three or four hours for the first twenty-four hours. The fluid is given through a soft rubber catheter attached to a DAVIDSON'S syringe and thrown in very slowly. In cases where there is flatus, quinine is given dissolved in the water. Under this treatment the thirst is much alleviated, the pulse regains its fullness and strength, and the shock seems to be combated much better.—*Pac. Med. Jour.*

Diet in Pregnancy.

DR. EICHMOLL, of Kreuznach, maintains that a large proportion of the discomforts and difficulties preceding, attending, and following parturition might be avoided by a rigid adherence to some simple dietetic rules. Excess of albumen and of water are, he considers, the errors against which pregnant women should be warned, as tending respectively to excessive development of the foetus and secretion of amniotic fluid. His rules are: Meat only once a day, and that in small quantity, and rarely if ever salted; green vegetables, salad, potatoes, bread and butter, but avoiding, as far as possible, eggs, peas, and beans as being too rich in albumen. Thirst is to be quenched by milk or water in very moderate quantities, cocoa is preferred to tea and coffee. Wine, beer, and spirits to be forbidden, and drink of any kind raising the sense of urgent thirst; but fruit, raw or cooked, to be indulged in *ad libitum*. The general result of such a diet he found to be a remarkable feeling of well-being; the sense of fulness, heaving down, and weariness, thirst and constipation, soon disappeared, and the patients have been able to walk many miles up to the end of confinement. His own wife would leap ditches and climb hills, and even on one occasion rode on a horse for an hour. The ease and rapidity of the delivery of several consecutive cases, some of whom had previously had difficult or difficult labor, the small amount of liquor amnii, and not more than a teaspoonful and sometimes less of liquor loquax were striking, and all without any special treatment. The children were healthy and well-nourished, weighing 7 to 8 lbs. and the placenta were of good size, 10 to 12 oz.

also noted, though not until the cyanosis had become quite marked; in fact, in the earlier years of cyanosis the increase in number was only relative. In individuals of from twelve to twenty years of age blood-counts of from 5,600,000 to 6,800,000 were found the diameter of the corpuscles varying from 7.9 μ to 13 μ . VACQUEZ does not think that the increase in number of the corpuscles was parallel to the increase in diameter, but thinks that both are due to the same cause. At the same time with the increase in size and number of the corpuscles, there is an increase in the amount of hemoglobin in each individual corpuscle, so that the hemoglobin does not show its normal relation to the number of corpuscles. The question as to whether the increase in size of the corpuscle or the increase in hemoglobin is the primary process cannot well be answered. The process has been explained on the grounds that in cyanosis the supply of oxygen carried to the tissues is insufficient, and that the corpuscular new-formation is compensatory. "In venous stasis the corpuscles are insufficiently oxygenated; they cannot perform such an active part as oxygen-carriers, and they cannot yield too much oxygen to the tissues. It must further be remembered that in cyanosis there is less metabolism in the tissues, and therefore less waste produced. In a word, the functions of the corpuscles being lessened, the wear and tear which they undergo are reduced and the duration of their individual existence increased. The number of the corpuscles must in this way be proportionately augmented, and this must lead to the numerical increase as well as to the high percentage of hemoglobin, until a balance is struck between the production and the destruction of the blood-corpuscles.—*The American Journal of the Medical Sciences.*

Nucleated Red Corpuscles in the Blood.

ZENONIS' experiments were made on dogs, guinea-pigs, and rabbits, in whose blood he had previously satisfied himself that there were no circulating nucleated red-blood corpuscles. He chose a dog weighing 6,700 klog., and in ten repeated operations withdrew from it a total of 1,830 c.c. of its blood then, after defibrinating the blood, he re-injected it into the circulation, and in an hour and a half after the operation noticed the appearance of nucleated red corpuscles, in the circulating blood, on examining a specimen under the microscope. He thinks that the rapid appearance of these corpuscles is due to the mechanical effect produced by the withdrawal of blood, for after repeated bleedings they appear too soon for their re-appearance to be due to a hematopoietic reaction; moreover, eight or nine days afterward they are no longer noticed, exactly when the hematopoietic reaction is at its maximum. He further thinks that after loss of blood these corpuscles are mechanically drawn into the circulation from their normal site, the bone marrow; that a certain number of them get stopped in the spleen, proliferate there, and give to the spleen that fatal hematopoietic function which has been ascribed to it by BIZZORZO as taking place after hemorrhage.

Influence of Coffee on Disease Germs.

PROFESSOR WAX arrives at the following conclusions:—

1. An infusion of coffee, when taken either as a beverage in the ordinary way, or with meat bouillon, undoubtedly acts as a disinfectant.
2. The disinfecting properties of coffee depend on the formation of certain overtones during the process of roasting; also on the tannic acid which it always contains.
3. The germicidal efficacy (such as it is) of acorn-coffee, rice-coffee, etc., is likewise developed by roasting.

4. An infusion of coffee or one of its substitutes made with water only, is a much better disinfectant than another of the same strength but mixed with meat bouillon.

5. A pure watery infusion of coffee of the same strength kills the bacilli of cholera within three hours, typhoid bacilli in one day, and the spores of the Siberian plague within nine days. Coffee substitutes, in like infusions, destroy the two former species of germs, but not those of the plague.—*N. Y. Med. Journ.*

Cheese a Carrier of Disease.

Not only is cheese liable to be poisonous by the development of tyrotoxicon, but it may prove to be a carrier of disease germs. DR. BEEBE, Assistant Chemist of the Board of Health in New York city, recently found the true bacillus of diphtheria in a lot of suspected cheese, and as the result of this discovery, a large quantity of the cheese was seized and destroyed.

It is said that there were several fatal cases of diphtheria in the family of a farmer who supplied much of the milk from which the cheese was made, and the germs conveyed by the milk from this infected house lived through the process of cheese-making, and communicated the disease to several who ate the cheese.

It has been known for a long time that milk was an excellent medium for the growth of bacteria, and therefore, of course, for the taking up of any infection and the spread of the same. No doubt many serious illnesses or diseases have been caused in this way, though traced supposedly to other sources.

The day is soon coming when no one will think of using milk without first pasteurizing or sterilizing it.—*N. E. Kitchen Magazine.*

Hansen's Leprosy Bacillus.

ACCORDING to the investigations of TSCHIELLA are present in the blood taken from or just near a leprosy tubercle but not in that taken at some distance from the leprosy manifestations, and the fact of its being found in tuberculous patients treated by KOHN's lymph though not in the blood of lepers similarly treated explodes LOEFFL's theory.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

The Hygiene of the Future.

THE great problems in medicine to-day are hygienic, not therapeutic, though therapeutics seem to be getting the better of diphtheria. The most desirable thing in the affairs of man is, first, the making of people healthy, and second, the making of them happy. The dyspeptic Puritanism which whines over the necessity of suffering as a means of grace can have no place in a superstition-free and scientifically enlightened philosophy. What we want, and what hygiene is yet to give us, are comfortable homes for all mankind, aseptic alike of the germs of symptomatic disease and of the taints of common vices, where noble and healthful men, noble because they are strong and healthful, and sweet and beautiful and healthful women, beautiful and sweet because they are healthful, shall rear their little families of disease-unbought children, happy because healthful, and giving promise of future attainment to the good, the beautiful, and the true—promise which shall not be broken because hygienic medicine has made the keeping of such promise possible.—*PROFESSOR H. A. COTTRELL, University of Louisville.*

Mental Labor Necessary to Mental Health.

EVERY one who desires to secure and to strengthen a healthy mind, must, first, not only labor physically but

also noted, though not until the cyanosis had become quite marked; in fact, in the earlier years of cyanosis the increase in number was only relative. In individuals of from twelve to twenty years of age blood-counts of from 3,600,000 to 6,800,000 were found the diameter of the corpuscles varying from 7.9 μ to 13 μ . VAQUEZ does not think that the increase in number of the corpuscles was parallel to the increase in diameter, but thinks that both are due to the same cause. At the same time with the increase in size and number of the corpuscles, there is an increase in the amount of hemoglobin in each individual corpuscle, so that the hemoglobin does not show its normal relation to the number of corpuscles. The question as to whether the increase in size of the corpuscle or the increase in hemoglobin is the primary process cannot well be answered. The process has been explained on the grounds that in cyanosis the supply of oxygen carried to the tissues is insufficient, and that the corpuscular new-formation is compensatory. "In various states the corpuscles are insufficiently oxygenated; they cannot perform such an active part as oxygen-carriers, and they cannot yield too much oxygen to the tissues. It must further be remembered that in cyanosis there is less metabolism in the tissues, and therefore less waste produced. In a word, the functions of the corpuscles being lessened, the wear and tear which they undergo are reduced and the duration of their individual existence increased. The number of the corpuscles must in this way be proportionately augmented, and this must lead to the numerical increase as well as to the high percentage of hemoglobin, until a balance is struck between the production and the destruction of the blood-corpuscles.—*The American Journal of the Medical Sciences.*

Nucleated Red Corpuscles in the Blood.

ZENKOWSKI's experiments were made on dogs, guinea-pigs, and rabbits, in whose blood he had previously satisfied himself that there were no circulating nucleated red-blood corpuscles. He chose a dog weighing 6,700 kilos., and in ten repeated operations withdrew from it a total of 1,880 c.c. of its blood then, after defibrinating the blood, he reinserted it into the circulation, and in an hour and a half after the operation noticed the appearance of nucleated red corpuscles, in the circulating blood, on examining a specimen under the microscope. He thinks that the rapid appearance of these corpuscles is due to the mechanical effect produced by the withdrawal of blood, for after repeated bleedings they appear too soon for their re-appearance to be due to a hematopoietic reaction; moreover, eight or nine days afterward they are no longer noticed, exactly when the hematopoietic reaction is at its maximum. He further thinks that after loss of blood these corpuscles are mechanically drawn into the circulation from their normal site, the bone marrow; that a certain number of them get stopped in the spleen, proliferate there, and give to the spleen that fatal hematopoietic function which has been ascribed to it by BIZZAZZO as taking place after hemorrhage.

Influence of Coffee on Disease Germs.

PROBODOWSKI arrives at the following conclusions:—

1. An infusion of coffee, when taken either as a beverage in the ordinary way, or with meat bouillon, undoubtedly acts as a disinfectant.
2. The disinfecting properties of coffee depend on the formation of certain essential salts during the process of roasting; also on the tannic acid which it always contains.
3. The germicidal efficacy (such as it is) of scorra-coffee, rice-coffee, etc., is likewise developed by roasting.

4. An infusion of coffee or one of its substitutes made with water only, is a much better disinfectant than scotch of the same strength but mixed with meat bouillon.

5. A pure watery infusion of coffee of the actual strength kills the bacilli of cholera within three hours, typhoid bacilli in one day, and the spores of the Siberian plague within nine days. Coffee substitutes, in like infusions, destroy the two former species of germs, but not those of the plague.—*N. Y. Med. Journ.*

Cheese a Carrier of Disease.

NOT only is cheese liable to be poisonous by the development of tyrotoxicon, but it may prove to be a carrier of disease germs. DR. BEEBE, Assistant Chemist of the Board of Health in New York city, recently found the true bacillus of diphtheria in a lot of suspected cheese, and as the result of this discovery, a large quantity of the cheese was seized and destroyed.

It is said that there were several fatal cases of diphtheria in the family of a farmer who supplied much of the milk from which the cheese was made, and the germs conveyed by the milk from this infected house lived through the process of cheese-making, and communicated the disease to several who ate the cheese.

Hansen's Leprosi Bacillus.

ACCORDING to the investigations of TISCHIELLA are present in the blood taken from or just near a leprosy tubercle but not in that taken at some distance from the leprosy manifestations, and the fact of its being found in tuberculous patients treated by KOCH's lymph though not in the blood of lepers similarly treated explodes LOOPI's theory.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

The Hygiene of the Future.

THE great problems in medicine to-day are hygienic, not therapeutic, though therapeutics seem to be getting the better of diphtheria. The most desirable thing in the affairs of man is, first, the making of people healthy, and second, the making of them happy. The dyspeptic Puritanism which whines over the necessity of suffering as a means of grace can have no place in a superstition-free and scientifically enlightened philosophy. What we want, and what hygiene is yet to give us, are comfortable homes for all mankind, aseptic alike of the germs of zymotic disease and of the taints of common vices, where noble and healthful men, noble because they are strong and healthful, and sweet and beautiful and healthful women, beautiful and sweet because they are healthful, shall rear their little families of disease-unblighted children, happy because healthful, and giving promise of future attainment to the good, the beautiful, and the true—promise which shall not be broken because hygienic medicine has made the keeping of such promises possible.—PROFESSOR H. A. COTTILL, University of Louisville.

Mental Labor Necessary to Mental Health.

EVERY one who desires to secure and to strengthen a healthy brain, must, first, not only labor physically but

...and that daily, and not the field... being fit together too... his mind in enjoyment and freedom, and... He will accustom... until they burden his mind. He will become more and more dependent and... His mental horizon will grow narrower continually and... The plastic brain of youth, that is, its docility and adaptability, will become less and less active and capable of comprehending and elaborating new thoughts. On the other hand, mental labor preserves the plasticity of the brain to a much more advanced age. Idlers, therefore, in spite of the best brain capacity, become prematurely old mentally, narrow-beamed, limited in horizon, and not seldom absolutely stupid. We often observe moderately gifted students becoming, by means of work, men of power; and highly gifted young men, by means of idleness, gradually grow useless, peevish, and now and then narrow-minded. "Nervousness," really brought about by means of mental overwork, forms only a small and comparatively safe fraction, while the great innumerable company of mental wrecks nearly always owe their catastrophe to diseased or defective brain conditions, to excesses, and an enormous percentage to alcohol. Professor HILTZ is certainly right, for he believes that the happiness of an individual (and he might have added his health also) depends upon his fulfilling the purpose of life by labor.

VOLTAIRE'S motto was "Always at work;" CARLYLE says, "Work alone is noble." CHARLES LAMB gives this warning: "No work is worse than overwork; the mind preys on itself—the most unwholesome food."—*Union Signal*.

Infection by a Midwife.

A WOMAN died of septicæmia after confinement and at the inquest the Blackburn District Coroner found that the septic infection that killed the woman was probably conveyed by the midwife going straight from one patient to another without disinfecting herself.

A Medical Witness.

In a Tacoma court, being asked whether medicine was an art or a science, replied with a sigh that it was neither one nor the other, but as yet merely an experiment.—*N. Y. Record*.

Syphilis in the Army vs. Licensed Prostitution.

In the French army the largest proportion of venereal disease was found in 1875—74 per 1,000. In the English army the proportion was 139 per 1,000. The highest figure was reached two years later, 374 per 1,000; while in the French army the figure stood as low as 52 per 1,000. From the figures the speaker concluded that venereal disease is much more frequent in countries where free prostitution exists than in those where it is licensed. This opinion might easily be learned *conversim*, but it would not make an argument in favor of licensed prostitution for several reasons. In the first place, some of the best medical authorities have spoken freely against licensed houses, asserting that they are no guarantee whatever against venereal disease, and an agitation is being set on foot in urging the Government to close them. His own official experience was that gonorrhœa was the inevitable result of a visit to one of these institutions. He could not have sworn as to syphilis, but he had known of several cases during the same years. Secondly, these houses are not under medical supervision, and the midwife is ready to supply all the means for the infection. Again, it should not be inferred from these statistics that the English

soldier is more virtuous than his French equivalent. The French soldier, if he had the means, can provide himself with a mistress—an institution unknown, as a rule, to the English soldier. Chastetude prevails in France by the increase in France, especially since restrictions have been in a great measure removed from the opening of liquor shops.—*Edin. Med. Jour.*

THERAPEUTICS AND PHARMACOLOGY. Typhoid Antitoxin.

PRIFER AND BEUMER at the Congress for Internal Medicine at Munich, referred to their earlier experiments, which showed that the toxin of typhoid cultivation is contained chiefly in the bacilli themselves; for after passing a cultivation through a Chamberland filter the filtrate was less virulent than before. The bacilli are killed, without damage to the virulence of the cultivation, by warming for an hour at 55° to 60°C. Their recent experiments show that by repeatedly injecting small quantities of virulent cultivations into sheep, antitoxic substances are formed in the organism which prevent the poisonous action from showing itself. The action of this antitoxic serum depends on its power of destroying, not the bacteria, but the poison. By injecting previously or at the same time antitoxic serum, mice and guinea-pigs were protected with certainty against double or treble the fatal dose of a virulent cultivation, and even if injected with the antitoxin one to four hours after the fatal dose was given, they could be cured.—*R. M. J.*

Glucose as Food.

DR. E. H. BARTLEY criticises the long-accepted opinion, that commercial glucose is suitable as a food. This opinion was promulgated some years ago by a committee of American chemists, appointed partly under Government auspices, and has been made the basis for justification of much substitution and adulteration. In the same way the opinions of some eminent chemists in favor of oleomargarin have been extensively quoted in defence of that article. DR. BARTLEY points out that mere chemical knowledge or even experiments on the lower animals or healthy subjects for a brief period are not sufficient to establish the harmlessness of a substitute food. Glucose made from starch by the action of acid is not the same as the product of digestion by animal ferments, and it is not likely that it will be a satisfactory substitute for the forms of sugar that arise in the process of normal digestion.—*New York Med. Jour.*

Gonorrhœa.

If seen during the inflammatory stage, give aloin pills 1 grain (0.065 gramme) each, to produce active purgation. This is an important point often overlooked. Not only does the aloin improve the appetite, but it also prevents chills and gonorrhœal synovitis, and renders the inflammation less severe. Twist a fine layer of cotton wool about a lucifer match, cover it with ointment made of dilute nitrate of mercury to which morphine has been added, 1 grain to the ounce (0.065 gramme to 31 grammes), and pass into the urethra three or four times a day. At the same time give an alkaline mixture containing hyoscyamine. Should the cure not be seen until three weeks have passed, give injections of liquor plumbi subacetatis, 1 drachm (4 grammes) to 4 ounces (160 grammes) of chloroform-water, with small doses of an emulsion of cod-liver oil, by the mouth. Give aloin to prevent the dysuria and pain in the urine caused by the copals.—*Brit. Med. Jour.*

Treatment of Burns and Scalds.

In emergency cases of dermatitis ambustionis of the second degree, i.e., burns and scalds, the old-fashioned castor oil, or corn starch, with the addition of boric acid, oxide of zinc, salicylic acid, bismuth, dermatol, etc., is far more effective and reliable than iodoform. Or, if lotions or the continuous bath are used, solutions of boric acid or liquor aluminii acetici (ten per cent.) are preferable to solutions of carbolic acid, sublimate, etc. In herpes zoster, simple corn starch, dusted on freely and bound down carefully by the aid of a thick layer of absorbent cotton, is by far the best treatment. In two cases of this disease I have seen the lesions break down and an extensive dermatitis develop under a dressing of iodoform gauze. In a case of intertrigo between the legs of a female infant, a dressing with carbolic acid gave rise to deep ulceration.—DR. F. J. LEVISEUR in *N. Y. Med. Rec.*

The Cold Bath in the Pneumonia of Children.

M. COMBY calls attention to the excellent effects yielded by balneotherapy in the pneumonia of quite young infants. Applied at a temperature of 25° or 20° C., according to age and circumstances, the cold bath is most serviceable in reducing the temperature, restoring lost tone, and slowing the pulse and respiration. Chemical antithermic agents, such as antipyrin, quinine, &c., are generally useless and may be dangerous. In his wards M. COMBY gives cold baths to all his little pneumonic patients whose temperature exceeds 39° C. (102.2° F.) and whose hearts are not diseased. Quite recently he had an opportunity of noting the good effects of this treatment in a little boy affected with influenzal pneumonia of the right apex, uninfluenced by ordinary antithermic drugs. M. COMBY adds that baths of 25° C. are quite well supported by even very young infants. M. SEVESTRE states that the application of the above method of treatment determines the onset of the crisis, on the fifth instead of the seventh day and so materially shortens the duration of the disease. M. RENDU also characterises the cold bath treatment as the best means of obtaining prompt deferescence in the pneumonia of adults. M. SIREDEY informs us that at the Ambervilliers fever hospital he has derived great advantage from the employment of cold baths in the treatment of broncho-pneumonia, consecutive to specific fevers, and M. Le GENDRE made a statement corroborative of their efficacy in all congestive complications of eruptive fevers. Professor HAYEM says that at the Hospital St. Antoine the most fatal disease of all is pneumonia, and that eighteen out of twenty of these patients are "alcoholics." During the first two years, 1879-1880, of his physicianship at that hospital he lost 50 per cent. of these cases. He then instituted the cold bath treatment and the mortality fell to 27 or 28 per cent. For some time past this mortality has further diminished (to 8 or 10 per cent.), but this improvement he ascribes to a new special treatment he has devised for the benefit of these alcoholic patients. Employed in the *criche*s attached to his wards, Professor HAYEM finds the cold baths more powerful for good against pneumonia than when used for adults.—*Lancet*.

Boiled Wheat with Lemon Sauce.

SELECT newly cut wheat, well rubbed or threshed out. Look it over carefully, wash, and put to cook in five times its measure of water. Cook gently until the grains burst open, and can be readily washed between the fingers. This will require from four to ten hours, the time depending upon the age and variety of the wheat used. To prepare the sauce,

heat a pint of water in the inner cup of a double-boiler. Soak this, when boiling, stir a dessert-spoonful of gum-starch, previously rubbed smooth with a little cold water, each five or ten minutes, until it thickens. Score a large lemon with the tines of a silver fork, and when the oil is swelling, add a small quantity of sugar over the surface, to flavor it. Afterward cut the lemon and squeeze the juice from it. Add the juice and one half-cup of the flavored sugar to the hot corn-starch mixture, allow the whole to boil up once, stirring constantly, then take from the fire and serve hot or cold on hot grains.

Fruit Tapioca.

Cook three-fourths of a cup of pearl tapioca in four cups of water until smooth and transparent. Stir into it tightly a pint of fresh strawberries, raspberries, or currants, adding sugar as required. Serve cold with cream, or a pudding sauce, prepared by heating a pint of the berry juice to scalding and stirring into it a tablespoonful of cornstarch previously rubbed to a cream with a little cold water. Cook until it thickens, then add sugar according to the acidity of the fruit. Strain and cool before using.

Correspondence.

MR. HART ON THE MEDICAL SERVICES.*

TO THE EDITOR "ENGLISHMAN."

SIR,—You have published in full MR. ERNEST HART's address at the annual meeting of the British Medical Association in London, and I ask you to permit me to reply to some of his remarks. MR. HART is a typical example of the "Paget, M. P. class of winter visitor" to India. He came out full of preconceived ideas, spent a few months here, chiefly employed in collecting facts in support of these ideas, and went home and claimed to be an expert on matters Indian from "a study of the health conditions of India." He made, to my knowledge, no study of the social conditions of Indian native life; he never visited an Indian village, or an Indian jail, or an Indian hospital, at least during his stay in Calcutta. He took in nothing in respect to the binding trammels of caste prejudice among the natives, and as regards the facts of native life of the millions of India he is almost as ignorant as if he had never left London. And yet he presumes to lash the Indian Medical Service and Indian officials generally on account of their neglect in not having introduced sanitary reforms which are only just becoming understood in England.

We doctors understand the enormous debt the people of England owe, but recognise, to MR. HART and other pioneers in Sanitary Science. MR. HART is not reticent in his address on his personal claims to public gratitude; but we in India have yet to learn that preventable disease has been abolished in England; that the people there all boil their drinking water, and that typhoid fever, diphtheria, and other filth and waterborne diseases are as extinct as the Dodo. MR. HART came to India like ALEXANDER seeking fresh worlds to conquer. It is "official apathy and stolid resistance" with him that is the reason why cholera, malaria, and dysentery are still Indian scourges. If MR. HART had been able to fever a meeting of the Calcutta Municipality with a view to some sanitary

* I reproduced from the *Englishman*.

reform was under discussion, he would have realised the more than stolid resistance to change and reform of the natives mind. But in his opinion the Indian Medical Service is the culprit: its senior officers know nothing of Laveran's bodies, or treat them with contempt; they never heard of the good effect of boiling drinking water, though this is a common practice in Anglo-Indian households, and therefore a service which has done as much as any other towards the civilisation and sanitation of India is to be abolished in its present form.

MR. HART conveyed what he must have known would be an entirely false impression when he told the London meeting that there was "no civil medical service in India," that it was only "a military service dislocated and called civil to hide its defects." He was usually the guest while in India of these civil military medical officers, and probably saw them going to official functions in uniform; he concluded, therefore, that these men were no doctors or civilians, they were only military officers. If he had taken the trouble to look at a Civil List he would have found that most, if not all, of them had spent nine-tenths or more of their service in varied civil employ, and were thoroughly acquainted with native life, native wants, native ways, and native prejudices. But such knowledge did not suit him: *delenda est Carthago*: these men are ignorant soldiers, they know nothing of Laveran's bodies or of the value of the tea kettle, they must be sent back to doctor sepoy in the regiments from which they should never have been withdrawn. All the good work of the Indian Medical Service in its civil branch, for the last hundred years, in infusil dispensaries and jails, in vaccination, in medical schools where European medicine, surgery and midwifery have been taught, and in endless other ways, is overlooked because the sanitary service and conditions of primitive India are not up to the European scientific standard. I do not say condition, for we know that Europe is still far from perfect in spite of the efforts of Mr. HART and his colleagues during the past thirty years. Another Royal Commission is demanded. In spite of the results of the Opium and the Hemp Drugs Commission, Government is to maintain a civil medical service not liable to military duty in case of emergency, promotion is not to go by seniority but by merit, good ordinary work of long years of service is to be ignored unless a man is familiar with the latest microbe discovered by some leisured scientist at home.

Truly the burden laid upon us out here by the faddist globe-trotter is becoming intolerable. There are facts of Mr. HART's address which are undoubtedly true—his criticism of the army regulations regarding cholera, though he omits to notice the fact that these do order the boiling of drinking water; his appeal for pure water-supply and proper filtration of water, his desire for a really scientific investigation of outbreaks of cholera and typhoid fever—but he blames the Indian Medical Service for errors regarding British troops and seems to be ignorant, though he has spent some months in India, that all matters regarding British troops are in the hands of the Army Medical, not the Indian Medical, Service.

MR. HART acknowledges "the remarkable ability, the enormous power of work, and the excessive overwork of

Indian Medical Officers," but these attributes are apparently only those of the juniors, for when these same officers become seniors, say at the age of 50, or 20 years younger than Mr. HART himself, "they are scientifically and administratively incapable of fulfilling the positions to which they have risen; by reason of their age and antiquated notions." It is a pity that Mr. HART, should have spoiled a truly useful address by his unworthy attack on the Indian Medical Service. One of Mr. HART's extremely practical suggestions when out here was that the zemindars in all villages throughout the land should be made, or urged to make arrangements for providing boiled drinking water for all their tenants, a common boiler and a common cistern for all the inhabitants of each village—from which the Brahman and the Dome, the Hindu and the Mussulman shall take their supply!—the zemindar, of course, paying the whole cost, the upkeep and establishment necessary. The caste prejudices regarding drinking water are also of course a matter of no moment, nor is the cost.

If these well-meaning reforming globe-trotters would only take the trouble of trying to understand the differences between the people of India and the people of Europe, the difference in customs and habits due to race, religion, climate, etc., and would temper with a small amount of commonsense their recommendations, we should welcome their suggestions and value their help in our arduous task of improving the physical, sanitary, and social conditions of a poor Oriental country.

I have known Mr. ERNEST HART personally for over thirty years. He was Dean of the School when I entered at St. Mary's in 1864. I have often met him when I have been at home on furlough, and have spoken to him of his long proposed visit to India, and he was my guest for nearly a month last cold weather; but I consider it is all the more my duty to call attention to Mr. HART's inaccuracies and deficient knowledge when he makes such an attack as that contained in his address on the service to which I have the honor to belong, and in which, alas! I must now have become an antiquated and incapable senior

Yours, &c., C. H. JOUBERT, M.B., London, F.R.C.S.,
Surgeon-Lieutenant-Colonel.

CALCUTTA, 28th August 1895.

II.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—MR. HART's address before the British Medical Association seems to have roused a veritable hornet's nest if I may judge by the various letters, evidently emanating from the pens of official medical men, but published in the local *dailies* under pseudonyms such as "Fair Play" &c., that might convey the impression that the writers were private practitioners.

I do not hold with a weather cock spirit, nor can I admire a policy that simultaneously blows hot and cold, nor yet forget that the printer's ink is barely dry on the unjust, terrific and insulting onslaught made by Mr. ERNEST HART against the civil medical practitioners of India, but I cannot but agree with the main issues of his contention that as round pegs cannot fit square holes, the medical services badly need re-casting, and that the

Commissioned Medical Service is not by any means so heavily overburdened as the Commission is pleased to be.

FAIR PLAY (say) and one or two other spectroscopic Mr. HART and declares that in reviewing the medical services of India he has hopelessly muddled the Army and the Indian Medical Services, together by speaking of them as the *Military Medical Services*. What a spitting of bile! A distinction with mighty little difference as both the A. M. S. and I. M. S. are military services and both hold pseudo-civil appointments in which they are expected to squeeze the duties of from 100 to 300 hours into a meagre working day of 8 hours (at most) and the energy obtained by the bodies of each one of them is supposed to be infinitely more than what Nature supplies for at least a dozen other human beings—the difference lies only in the fact that the A. M. S. was created for the British and the I. M. S. for the East India Company's troops.

True, Sir, quite true, that the routine work laid down for the Commissioned Medical Service is really heavy—so heavy indeed that they would die under it in less than a month if they only did a *sixth* of the work the regulations lay down they *should* do. That the work is done there is not the least doubt. But *who* does it? The Surgeons (Lieutenants, Captains, Majors) &c? No certainly not, they are gazetted "in charge," and it would be derogatory to them to do more than supervise, sign statistical and requisition forms, write up an occasional case or report: else they could not possibly find the time for polo, theatricals, more private practice than State work and lengthy disquisitions, for public aggrandisement, in the lay journals.

Now, Sir, if instead of coming out to India and rushing hither and thither after PASTEUR filters, fine theories and bacillar chambers, had Mr. HART visited the great hospitals of India, *in person*, he would have been in a far better position than he now is to render unto Caesar what should Caesar's be, and *wholly* agreeing with me that infinitely more work of a *better* quality would be done besides a *huge* saving effected were the medical services reduced by, at the very least, *three-fourths* of the numerical strength they now obtain, he would never have ignored the Civil Hospital Assistants and Military Assistant Surgeons, on whose shoulders devolves the *whole* of the heavy work with which the Commissioned Medical Service is so overburdened.

In a letter to the *Englishman* (28th August 1895) Surgeon Lieutenant-Colonel C. H. JOUBERT, M. B. &c. inveighs bitterly against Mr. HART's demand for a re-constituting of the medical services and, in so doing, does the very thing, he would heavily deprecate in a private practitioner, i.e. washing professional dirty linen in the columns of a lay journal and flaunting his academic qualifications. Dr. JOUBERT resists recasting; but let him change places with the civil practitioner and ask him whether as a man he can honestly say that Mr. HART is utterly wrong in condemning a military hierarchy and insisting that the military services should be confined to the army, while work, not more specially, should be assigned to the granting of responsible official posts? Would he consent to let that a highly paid official be permitted to neglect his public duties and enter into open competi-

tioning a subordinate in the execution of his duties? Would he consent to let a subordinate who is not a member of the medical profession to criticise his official duties? Would he consent to let a subordinate give any valid reason, however plausible, for his own existence? Holding a military rank and Commission in the Indian Medical Service will he still persist in declaring that he is not a military man because he is temporarily attached to the Civil list? Can he deny the existence of that year after year the Indian Colleges are turning out so smart and able men as have ever passed out from the medical schools of the West and that the majority of these men are in civil life? No! No! No! He can not.

I could say a great deal more, Mr. Editor, that cannot be disputed; but I fear I have already encroached a good bit on your space and must wind up by suggesting that if a Royal Commission be appointed for the re-organising of the Services, the evidence collected should be from every available source, civil and military, and not a one-sided farce, as are most of the Commissions, so far held.

My card herewith sir, to show that I am not afraid to stand by my guns, which are charged with irrefutable truths and while I have not the least objection to your divulging my name to individual enquirers I adopt a *feuille de plume* because I do not wish your 4000 odd readers to think I am trying to advertise myself as a fearless, plain-spoken and straightforward.

CIVIL MEDICAL PRACTITIONER.

CALCUTTA 6. September 1895.

DIAGNOSIS AND TREATMENT WANTED.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I shall be highly obliged if any one of your many readers can kindly inform me through the medium of your paper of the name and treatment of this disease, the symptoms of which I quote below. This will not only put me under obligation, but will mitigate the sufferings of many poor souls.

A peculiar oedematous swelling of both the feet first begins with some pustular or vesicular eruptions, which then burst, coalesce and excrete copious serous fluid. The swelling attains a large size, and the sufferers are unable to walk.

The vesicles and pustules turn into very painful, extensive patches but do not itch. Both the dorsal and plantar sides are affected. This disease is prevalent during the rainy season and among the laboring classes, affecting men and women alike, but the latter are more so. Sometimes two or three places of the swelling burst and copious fluid passing out causes agonising pain. The local name is "Phool Ki Bimar" or "Familara."

There is no doubt that some kind of parasite produces the disease, the exciting cause of which is wind and water, with which they constantly come in contact.

Damp and swampy lands are favorable places for the growth of the parasite.

We generally treat the cases, locally, with strong caustic solution. —

A. Argenti nitrate.

Sp. chas. nitrate.

M. Fl. India.

But this serves no purpose and is very slow to heal.
Please publish this letter as early as possible, as I am
in great trouble of mind.

Yours &c., BANKIM BEHARI CHATTERJEE,
In charge Kumbhir Hospital, Cachar.
CACHAR, 27th August 1895.

:O:

PROVIDENT MEDICAL FUND.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—On page 183 of the last issue of your estimable journal I saw exactly what we have been clamouring about for 3 years. I have sent you the formal notice you ask for, and I hope you will shortly be able to announce in your paper that you have had quite a rush of applicants from our department, to whose careful consideration I earnestly commend the project.

Yours faithfully,
GEO. WILSON.

JALALA, 9th September, 1895.

*The formation of a Medical Provident Fund.

:O:

THE SUBORDINATE MEDICAL DEPARTMENT.

TO THE EDITOR "INDIAN MEDICAL RECORD."

SIR,—With reference to the amalgamation of the above departments in the three Presidencies, can any of your readers inform me whether there will be only one general list for promotion for all Military Assistant Surgeons? As this arrangement would benefit only those now belonging to the Bombay Presidency, where the promotions are at present very slow, it would be very unfair to the subordinates of the other presidencies, more especially to the 3rd Class Assistant Surgeons in Bengal, who are now generally promoted to the 2nd Class within three years, whereas their compatriots in Bombay have to wait for seven and often even for ten long years.

SLAVE OF THE PESTLE.

Government Medical Gazettes.

BENGAL GOVERNMENT.

Asst.-Surgn. Nitro Gopal Mittra, in charge of Arrah Dispy., is to have additional med. charge of Shahabad, *vice* Surgn.-Lieut.-Col. W. F. Murray, on leave.

Surgn.-Lieut.-Col. W. F. Murray is allowed leave for forty-two days, from 15th Sept.

Surgn.-Lieut.-Col. G. Price, is allowed leave for one month and five days from 10th Sept.

Asst. Surgn. Krieto Charan Bose, in charge of Berhampore Dispy., to have additional med. charge of Murshidabad, *vice* Lieut. Col. G. Price, on leave.

Brig.-Surgn. Lieut.-Col. F. C. Nicholson, Civil Surgn. of Patna, is allowed leave for four months and fifteen days, from 20th May.

Mily. Asst. Surgn. C. R. W. Bancroft to act as Med. Officer Sandhead, *vice* Mily. Asst. Surgn. J. C. Gillmon, on leave.

Mily. Asst. Surgn. J. C. Gillmon is allowed leave for one month, from 24th Aug.

Surgn.-Capt. R. Bird, Asst. Surgn., Med. Coll. Hosp., to act as Professor of Anatomy, Med. Coll., Calcutta, in addition to his own duties. *Asst. Surgn.-Maj. R. H. Charles, on leave.*

PUNJAB GOVERNMENT.

Third class Hosp. Asst. Wali Muhammad Khan resumed charge of North-Western Railway at Nowshera, Peshawar Dist., on 16th Aug.

Second class Hosp. Asst. Talsi Ram reported himself to Civil Surgn. Peshawar, on 17th Aug.

Third class Hosp. Asst. Ram Rattan, Mebraj Dispy., Ferozepore Dist., is entitled to the higher rate of pay of his grade from 19th Aug.

Asst. Surgn. Mahta Devi Dial to the Mayo Hosp., Lahore, for gen. duty, 9th Aug.

Second class Hosp. Asst. Muhammad Ismail Khan, Kartalwala Dispy., Gujrat Dist., three months' privilege leave, from 18th Aug.

Third class Hosp. Asst. Khair-ud-din resumed charge of Police Hosp., Dera Ghazi Khan, on 18th Aug.

Third class Hosp. Asst. Fazal Elahi to the Oghat Border Mily. Police Hosp., Hazara Dist., on 21st April.

MADRAS GOVERNMENT.

Surgn.-Maj. John Maitland, M.D., to act as Senior Med. Offr. Genl. Hosp., Madras, *vice* Brig.-Surgn.-Lieut.-Col. W. Price, M.D., on leave.

Surgn.-Maj. John Smyth, M.D., to act as Surgn., Genl. Hosp. Madras, without prejudice to his own duties, during the employment of Surgn.-Maj. J. Maitland on other duty.

Native Mily. pupils to be admitted as Sub-Hosp. Assts. from 12th Aug. and promoted to the rank of 3rd grade Hosp. Assts. D. Munisawmi Mudaliyar, S. Audinarain, M. N. Somasundaram Pillai.

Surgn.-Maj. John Maitland, M.D., to act as Principal and Professor of Medicine, Med. Coll., *vice* Brig.-Surgn.-Lieut.-Col. W. Price, M.D., on leave.

Surgn.-Maj. John Smyth, M.D., to act as Professor of Surg. and Clinical Surgery, *vice* Surgn.-Maj. J. Maitland, M.D., on other duty.

BOMBAY GOVERNMENT.

The following 3rd class Hosp. Assts. are transferred from 9th Aug.—Bhimaji Krishna to Dharwar: David Joseph to Yerrowda Central Prison.

Third class Hosp. Asst. Kassinath Hari Modak, genl. duty, sick leave for one month from 1st Aug.

Second year mily. pupil Alfred Andrew Lowe, Grant Med. Coll., leave for one month from 27th July.

CENTRAL PROVINCES GOVERNMENT.

Third class Civil Hosp. Asst. Suraj Parshad Tiwari, Nagpur, to do duty under Civil Surgn., Bilaspur.

Third class Civil Hosp. Asst. Yado Rao, Mandla. tempy. to Dindori Branch Dispy., Mandla Dist.

First class Civil Hosp. Asst. Deen Mahomed, Dindori Branch Dispy., Mandla Dist., is tempy. to Jail and police Hosp., Mandla.

First class Civil Hosp. Asst. Ramcharu Lal, Main. Dispy., Mandla, held tempy. med. charge of the Jail and Police Hosp. Mandla, 25th Aug.

Third class Civil Hosp. Asst. Kazi Fak the Allapilly Dispensary Chanda District.

Hosp. Asst. Rameshrya Jaganath Dubey, attached to the Allapilly Dispy., Chanda District, to do duty under Civil Surgn., Chanda.

N.-W. P. AND OUDH GOVERNMENT.

Surgn.-Capt. J. Morwood, Civil Surgn. Basti, 2½ months' priv. leave from 20th Aug.

Surgn.-Lieut.-Col. A. J. Willocks, Civil Surgn., Agra, priv. leave for three months from 15th Sept.

Surgn.-Maj. J. Anderson, Civil Surgn. Bareilly, priv. leave for one month from 1st Sept.

Surgn.-Capt. G. H. Baker, Civil Surgn., Banda, priv. leave for two months, 3rd Sept.

Asst. Surgn. Sheoraj Misra, leave (*m. c.*) for six months from 13th April.

Asst. Surgn. Gobind Narayan Das, in charge Srinagar Dispy., Garhwal, priv. leave for one month from 14th Aug.

Asst. Surgn. Ikhtidar-ud-din, Haridol, leave (*m. c.*) for two months from 25th July.

Asst. Surgn. Nihal Singh, Rai Bahadur Saharanpur, priv. leave for fifteen days from 20th Sept.

Asst. Surgn. Trihlita Nath Singha to hold civil med. charge of Basti, during the absence of Surgn.-Capt. J. Morwood on leave.

Surgn.-Maj. C. P. Lukis, to officiate as Civil Surgn., Agra, *vice* Surgn.-Lieut.-Col. A. J. Willocks, on leave.

Asst. Surgn. Chandra Kanta Chakrabarti, Muzaffarnagar, to hold civil med. charge of that District.

Surgn.-Maj. D. F. Barry, Civil Surgn., Gorakhpur, to visiting med. charge of Bandi Dist.

Surgn.-Lieut.-Col. J. Armstrong, Civil Surgn., Cawnpore, to hold med. charge of Unao dist., in addition to his other duties.

Asst. Surgn. Rajendra Nath De, to hold civil med. charge of the Unao dist.

Third grade Hosp. Asst. Ram Prasad Bana, Karnprayag diapy, Garhwal, to charge of Srinagar diapy.

Asst. Surgn. Shashi Bhawan Banarji, Lucknow, to charge of the Banarji Haridwar dist.

First grade Asst. Karim Baksh, Saharanpur, to hold charge of the Sadar dispensary in that dist.

Surgn.-Maj. J. F. Tuohy, Civil Surgn., from Saharanpur to Bareilly.

Surgn.-Capt. H. W. Elphick, from Muzaffarnagar to Saharanpur, and to hold visiting med. charge of the Muzaffarnagar dist.

Doctor H. A. Macleod, Officiating Civil Surgn., from Unao to Banda.

Asst. Surgn. Bishambhar Sahay, on reserve duty at Lucknow, to the charge of the Sadar diapy., Sultanpur.

Asst. Surgn. Nil Ratan Banarji, on privilege leave for 3 months from 16th August 1895.

Asst. Surgn. Saraju Kumar Mukerji, attached to the Sadar diapy., Orai, held charge of the civil medical duties of the Jalau district from 1st to 22nd June.

Honry. Surgn.-Lieut. C. T. Leopold, in civil med. charge of the Jhansi dist. to the charge of the Civil Hosp. Allahabad.

Milry. Asst. Surgn. M. Murphy, in charge of Civil Hosp. Allahabad, to the civil med. charge of the Partabgarh dist.

BURMA GOVERNMENT.

Surgn.-Maj. George Tucker Thomas, to be Surgn. Lieut.-Col.

Surgn.-Capt. Arthur Owen Evans to be Surgn.-Maj.

The Chief Commr. appts. Dumree Lal, Hosp. Asst., to be a member of the Pagan Municipal Committee, *vice* Hosp. Asst. D. Philip, transferred.

Special leave for six months, on urgent private affairs, is granted to Surgn. Lieut.-Col O. Baker, from Aug.

Surgn.-Maj. O. S. Randle, to be Civil Surgn., Rangoon, and Supdt. of the Rangoon Lunatic Asylum.

Surgn.-Capt. C. N. Bensley, to be Civil Surgn. Thayetmyo.

Mr. C. Martin to be Civil Surgn., Tongoo.

First grade Hosp. Asst. G. C. Chuckerbutty, temply. in charge of duties of Civil Surgn., Pegu.

ASSAM GOVERNMENT.

The following 3rd grade Hospital Assistants are transferred:—Srihari Mukerji, to Mokokchang Diapy, in Naga Hills Dist. from 19th Augt.

Rajendra Kisor Chakravati, Tamlu Mily. Police outpost in Naga Hills Dist., from 10th Augt.

Afzal Hussain held charge of Mokokchang Diapy. from 2nd July to 18th Augt.

Brijdaban Chandra Datta, to Henema Mily. Police outpost, from 21st July.

G. O. C. C.

Hospital Assistant Muhammad Ibrahim Khan resigns the Sab. Med. Dept.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Re. 1 for subscribers and Re. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTH.

HORROCHS.—At Rasikhot, on the 7th September, 1895, the wife of Surgn.-Capt. Horrochs, A.M.S., of a son.

BARBER.—On the 24th August, at Gulmarg, the wife of Surg.-Capt. H. B. C. Barber, I. M. S., Civil Surgeon, Sialkot, of a daughter, still born.

DEATH.

STRATTON.—On Aug. 28th, at the Nevers-square, A.W., Brig.-Surg. John Frodoctot Stratton, M.D., Aberd., Indian Medical Service (Retired), aged 44.

NOTICES TO CORRESPONDENTS.

J. K. D. (Bellkot).—Kindly read *Business Notices*. Delay in notification retards our moving the postal authorities.

Indian Medical Provident Fund.—Since closing our pages for the press, four more names have been sent in of persons willing to join the fund. We need 100 names. Let others show their interest in the matter and send us a post-card, with their name and address clearly written, expressing their desire to join the fund.

A. S. (Merta).—Thanks for your paper.

C. F. P. (Melbourne, Australia).—You will find the Government Orders, altering change of designation of Military Assistant Surgeons in the *Record*, Vol. VII, page 81. Military Assistant Surgeons are Medical Officers duly appointed and confirmed on H. M.'s Land and Sea Service. We believe the new parchment Warrant will clearly emphasise this fact.

R. P. W. (Coloba).—Ft. dosis means let one dose be made. The first item is acid phosphate not phosphoric acid, which latter would be incompatible to the prescription you refer to.

H. K. S. (Raiganj).—The Association Certificates are being engrossed, and when ready will be duly signed and forwarded to members.

R. F. S. (Bareilly).—Please read the Association Advertisement in the *Record*.

G. E. C. (Nainital).—The full text of the Indian Medical Association Rules and memorandum will be found in the back numbers of the *Record*.

E. E. D. (Lucknow).—Your query is answered in this number.

S. D. C. (Surat).—We shall be glad to receive your paper and publish the same in this journal.

M. C. B. (Dagshai).—Saunders's *Materia Medica* and *Da Costa's Surgery* with the *Manual of Prescriptions* will answer your purpose.

S. N. G. (Jalapaahar).—Your matter will receive almost immediate attention.

S. K. M. (Orai).—Kindly read the Association Advertisement in this number and forward your Subscription to Surgeon Major H. C. Hodgkins B.A.S., I.M.S., Medical College Calcutta.

I. M. (Bombay).—We would be much obliged if you would inform us of your objections.

ACKNOWLEDGMENTS.

We acknowledge receipt of the following with thanks:

Literary Contributions and Letters from:—Dr. Ernest Hart, D.C.L., London; Surgn.-Capt. B. H. Elliott, M.A., B.S., F.R.C.S., D.P.H., Madras; Roger G. S. Chew, M.D., C.M., M.S.C., Calcutta; Surgn.-Capt. Patrick Hehir, M.D., F.R.C.S., I.M.S., Hyderabad; Asst. Surgn. A. Baile, I.M.S., Southampton; Asst. Surgn. M. G. Dams, I.M.S., Malacca; Bankim Bihari Chatterjee, L.C.M.S., Ball; V. S. Bahadur Mudaliar, C.M.S.; J. K. S. Cooper Barrow, M.A., Trichinopoly; Asst. Surgn. G. White, Jalaia; and others.

ORIGINAL ARTICLES.

CEREBRO-SPINAL FEVER.^o

By SURGEON-MAJOR JAS. MOORHEAD, M.A., M.D., I.M.S.,
Civil Surgeon, Simla.

I HAVE ventured to select cerebro-spinal fever as the subject of this paper, because, in the first place, the disease so named has only been recently seen or reported in India, and because, in the second place, the disease, as seen here, differs, so far as my experience goes, in some very important features, from that as observed in other countries.

This specific and deadly fever has been known under various names: it has been described as spotted fever in America and as cerebral-typhus in Germany; it has been described also under the names of epidemic meningitis and epidemic cerebro-spinal meningitis; it has been popularly known as "the black sickness" in Dublin and as "nackensterre" or stiff neck in Germany. The name I have adopted is that which has been given by the London College of Physicians.

The history of this disease in Europe goes back for certain, for nearly one hundred years, and there is some reason to believe, ATKEN tells us, that it goes back even as far as the fourteenth century. The first well ascertained epidemic occurred at Genoa in 1805, and in the following year it appeared in the United States, and continued to prevail there for ten years. During the same time, and off and on during the past half century, it was observed in France, in Italy, in Spain, and in Denmark. In 1854, and for seven years afterwards, it raged in Sweden, where it is said to have destroyed more than 4,000 persons.

In 1860 to 1870 it shewed itself again in America, in 1863 it broke out in the Northern Provinces of Prussia, and from that time it has hardly ever ceased to shew itself in some part of the German Empire. The British Islands have hitherto enjoyed a remarkable immunity. Scotland, it is said, has never been attacked, only a few isolated epidemics have occurred in England, and though the disease has twice appeared in Ireland, once in the famine year of 1846, and again in 1867, it was seen chiefly among the inmates of a few work-houses and among the recruits of the Royal Irish Constabulary, stationed in Dublin.

Here, in India, the disease has been practically unknown, until within the last fourteen years. Chevers, in his work "Diseases of India," tells us he only met with one doubtful case, which recovered, and that neither Ewart, nor Guodere, nor Duka ever saw a single case, though the two latter had watched sedulously for this disease. Cerebro-spinal fever appears for the first time in 1881 in the returns compiled by the Sanitary Commissioner with the Government of India. Since then, up to 1892, 333 cases with 259 deaths have been shewn, as having occurred in the army and in jails. The Sanitary Report for 1893 has not yet been printed, but Surgeon-Major Lewtas, Statistical Officer, has kindly informed me, there were in all fifteen cases with ten deaths. The figures I have just given do not represent, I believe, the actual prevalence of the disease, as cases and deaths, under the head of inflam-

mation of the cerebral membranes, figure largely in the returns, during the past ten years, and I have little doubt many of the cases and deaths thus shewn would more correctly have appeared under the name of the disease I have chosen for this paper. I see, for instance, in 1886, inflammation of the cerebral membranes is reported to have caused eighteen admissions with fifteen deaths in jail, and eighteen admissions with twelve deaths in the army. European and Native; and, again, in 1887, under the same heading, appears seventeen admissions with seven deaths in the army.

Cerebro-spinal fever in a sporadic form has been very widely distributed throughout India, none of the three presidencies having completely escaped. The disease has also appeared in Burma and in the Andamans and Nicobars. The outbreaks, however, have been practically confined to Bengal and Bombay, only one case having been reported from Coimbatore, in Madras. Jails have suffered chiefly, only three cases with one death having been reported in the European, and twenty-one cases with fourteen deaths in the Native army, during the last thirteen years. The Bengal jails have suffered most, one-fifth of the total jails in the province having been attacked. The Alipore Central Jail has returned several cases and deaths every year since 1886. Of the Bombay Jail, Shikarpur has been chiefly attacked; and among the jails of the Punjab, the disease has been seen chiefly in the Central District Jail at Lahore.

How far, if at all, the civil population are affected, we have no data to judge from. The disease has no place in the returns of civil hospitals and dispensaries.

My first practical acquaintance with cerebro-spinal fever dates from 1889, when I was in charge of the Hazaribagh Jail. In that year there were two outbreaks in the jail, the first occurring in May and June (first case 18th May, last 5th June) the second in October and November (first case 8th October, last 8th November).

In each outbreak there were seven cases, six deaths occurring in the first and five in the second. I met with the disease again in 1891 and 1892, while in medical charge of the Bhagnipur Central Jail. There, however, I had only two cases, one of which recovered. I have had in all sixteen cases with twelve deaths.

I shall now try to give you the results of my observations, and shall also endeavour to contrast the disease as seen by me and described in books. I have had no opportunity of reading the reports of other Indian medical officers, except the very brief extracts that have appeared in Administrative Reports, and so am unable to say how far their experience coincides with or differs from mine.

First, as to clinical history. The disease, as a rule, sets in suddenly with symptoms like those seen in severe malarious fever, the temperature quickly rising to about 103° F., though it may run up to 105° F., as it did in one case. The course of the fever is very irregular, sometimes the morning temperature being the same as the evening: sometimes one or two degrees less; and occasionally higher. When it is prolonged over several days the temperature falls and becomes more or less remittent, the range being from about 99° F. to 102° F. A special rise

^oBeing a paper read before the Indian Medical Congress and sent to the Record for publication.

towards the last, such as is mentioned by FAOON and PYS SMITH, occurred in none of my cases.

Nervous disturbances always occur early, and soon become prominent. Pain, which may be most excruciating, is early felt, sometimes all over the body, sometimes only in the joints, but as a general rule in the head. In a small proportion of the cases, pain in the neck and back was a prominent symptom.

Delirium, accompanied in some cases by great restlessness, but not of a violent type, occurred in half or more of my cases. It began in one case in ten hours; in a second, in twelve hours; in two cases, after twenty-four hours; in a fifth case, after forty-eight hours; in a sixth, after sixty hours; in a seventh, after eighty-four hours; and in an eighth, not till the fifth day.

Coma was present in ten of the fatal cases; it was present also in one case that recovered, lasting for about sixty-two hours. This condition may supervene at a very early period; in one case it set in within three hours from the commencement of the fever. As a rule, it was preceded by delirium, and where such was the case it followed in from about twelve to forty hours from the commencement of the latter. The comatose condition persisted in almost all cases till death. Consciousness was partially regained after eight days: in one case that survived twenty-one days, and completely after five or six days; in a second case that lived thirty-one days. In the latter case, though consciousness began to return after three days, the patient was unable to speak for another six days; then for five days he continued able to speak, but again became comatose and remained in that condition for sixty hours; again consciousness returned, to be followed again after thirty-six hours by coma. Alternations of these conditions occurred almost daily for five days up to the patient's death on the 31st day of the disease. The coma in all cases, except one, was unaccompanied by stertor; deep groaning was present in one case.

Retraction of the head occurred in only three cases, and was present in one of the patients that recovered. This symptom appears to have been more frequently met with in other countries. FLINT tells us it has been observed in eighteen out of sixty cases, and English authorities describe it as still more frequent. Opisthotonos was present in no case, neither was trismus; this latter, according to FLINT, has been observed in 17 out of 60 cases. Rigidity of the rectus abdominis in a marked degree was present in one case that recovered.

Convulsions (clonic) occurred in one case that survived 31 days shortly before death, the contractions sometimes occurring in the upper extremities, sometimes in lower, and sometimes only in particular muscles.

Vomiting, which is mentioned in books as an early and very common symptom, was absent in all my cases, except two, and in these it occurred only shortly before death; pain in the stomach was very rarely specially complained of. *Uneasiness*, however, with or without puffiness, was an early symptom in five cases; constipation was present in some cases, while in two cases the bowels were relaxed.

Parotiditis, with effusion, was present in ten of the twelve fatal cases; it was present in two cases that sur-

vived only ten and twelve hours after the commencement of the attack. This complication is not mentioned either by ATKIN, by ROBERTS, by QUAIN, or by HOWARD SMITH. FLINT, of New York, mentions it, and so do FAOON and PYS SMITH, but the latter say it is dependent upon secondary pyæmia. This view, however correct it may be, generally, is not applicable to the two very early fatal cases I have just mentioned.

Lung complications were present in the five of the fatal cases and in one that survived in two of the cases there was pleuro-pneumonia, and in other three congestion or red or gray hepatization in one or both lungs. In one case that survived there was congestion of the right lung about the seventeenth day of the disease. It is worthy of notice that in no case was there the characteristic sputum of pneumonia, and that cough was not present except in one case. The respirations, however, in one case, were as many as fifty-two per minute.

Hearing was much impaired in one of the surviving cases, in which consciousness was never lost; in the same case, articulation was very difficult, and there was considerable impairment of the mental faculties for months after convalescence began. Difficulty in articulation was also noticed in one case that proved fatal.

Retention of urine were present in two cases.

Eruptions, which appear to have been common in other countries, were noticed in none of my cases; the same remark applies to eye complications.

Next, as to morbid anatomy. Morbid changes were present in the membranes of the brain and spinal cord in the lungs and pericardium. In the first mentioned, the appearances varied a good deal: the one case that survived twenty days, the vessels of the pia mater were markedly shrivelled; and in a second case, that lived thirty-one days, contraction of the same vessels was noticed. The examination in the former case was made within two hours, and in the latter within one hour after death. In six or seven of the cases there was intense congestion of the membranes, the veins at least in one case being filled with partially coagulated blood. In the two cases that survived over twenty days, the sinuses at the base of the brain were practically empty; in all the other cases examined, some of the petrosal sinuses contained partially or completely decolorized coagula. A fibrinous clot, 8 inches long, was, in one case, drawn out of the right interior petrosal sinus. An exudation, varying in character and extent, was present in all the cases examined, except two: in one case, that died after twelve hours, it was clear and gumlike; in another, that lived twenty-one days, it was starchy in color; while in all the others, it was distinctly yellow; in a few cases being purulent or semi-purulent. The extent of the exudation varied much: in the case that survived thirty-one days, there was only a trace of lymph over the pons varolii, and inferior perforated spot also between the posterior surface of the medulla oblongata and the cerebellum. There were, however, several points of purulent infiltration on the convex portion of the right hemisphere, close to the longitudinal fissure, one smaller point on left hemisphere, and about fifteen drops of actual pus in each posterior horn of the lateral ventricles; in another case that lived only

ten hours; the exudation was present in two or three of the sulci of the convex portion of the right hemisphere, and in one or two of the left in a similar position. In these situations it was very distinct and of a yellow color. As a rule, the exudation was present along the base of the brain, continuously from the medulla oblongata to the optic commissure; in one case it reached to a point anterior to it; and in a second it surrounded the pituitary body; it was present also in several of the sulci of convex portions of the brain and sometimes over the floor of the fourth ventricle and between the holes of the cerebellum. The brain itself only presented numerous points on section; in one case there was no sign of softening. It is probably, however, the superficial layers of the cortex are to some extent affected in the diseased process.

The membranes of the spinal cord also varied a good deal in appearance: in the case that lived thirty-one days there was neither congestion nor exudation; in three cases there was congestion only; while in six or seven cases the cord was partially or completely surrounded by a more or less distinct layer of lymph exudation. The exudation in all cases was yellow, except one, in which it was clear and gumlike, that formed in the membranes of the brain. In one case the exudation was continued over the cauda equina. In one case about 2oz. of puriform fluid escaped, on section of the membranes in the cervical region, and similar fluid was formed in the lumbar region of the same case; in another case there was a quantity of actual pus in the lumbar region. The spinal cord itself was not noticed as softened.

The condition of the lungs varied also in the two cases that survived over twenty days, both were intensely anæmic, in fact almost bloodless: in five cases no unusual appearances were noticed, while in the remaining five fatal cases, very distinct morbid changes were present. In one, that of a man who died in four days, the whole of the right lung was hepatized, the upper lobe being in a state of grey hepatization, and the whole of the left lung was greatly congested, though no part was solidified. In a second case, both lungs were congested, the right being adherent to the chest wall by recent lymph, a small portion of the lower lobe of the same lung being in a state of red hepatization. In a third case, the left lung was adherent to the chest wall almost throughout by a very thick layer of, recent, yellow lymph, a portion of the lower lobe of the same lung being in a state of red hepatization, the right lung was congested and the right pleural cavity contained about 5oz. of serous fluid; in a fourth case, part of the right lung and the whole of the left was congested, and portions of the latter hepatized. In the fifth case, the left lung only was congested.

The pericardium in ten out of the twelve fatal cases, contained more or less serous fluid, with or without congestion of its lining membrane. There was, on an average a little over 2oz.; even in the two cases that survived ten and twelve hours, quite 2oz. or more were present.

Both ventricles of the heart contained, in one case large fibrinous clots, and in another non-fibrinous clots were present. In addition to the morbid changes already described, I may add that the liver was noted as enlarged in four cases, its weight in one case being 3lbs. and in

another 3lbs. 19s. The spleen were also enlarged in four cases, but the condition existed in one, if not two of the prisoners before being attacked.

The diagnosis of cerebro-spinal fever, at the commencement of an outbreak, is sometimes by no means easy. LAYREN tells us that an outbreak of typhoid fever among the German troops, before Paris, in 1870, was at first mistaken for cerebro-spinal fever, owing to the presence, in a series of cases, of marked rigidity of the neck, severe headache, hyperæsthesia, low temperature and constipation, but that the autopsies demonstrated the real nature of the disease. Here, in India, the only disease for which it is likely to be mistaken is a severe malarious resultant; and, I think, it must be admitted that a positive diagnosis from that disease is hardly possible, till a post-mortem examination has been made. The excruciating headache and backache, the irregularity of the temperature, the early setting in of delirium followed by coma, and the rapidly fatal character of the disease are the points that may be most relied upon.

The prognosis in India is very unfavorable; there were 15 deaths out of 17 cases in jails in 1892 and 29 deaths out of 35 cases in 1891; in the latter year, there were eleven cases in the Alipore Central Jail, all of which proved fatal. The mortality in my cases was somewhat less, being only 75 per cent. In Europe the general prognosis is less unfavorable, the mean mortality being only about 40 per cent. though in some epidemics, as four-fifths of those attacked have died. The range of temperatures assists a little in forming a prognosis; in my most rapidly fatal case 102·6° F. was the highest temperature recorded.

The early setting in of coma is an unfavorable symptom, but one of my cases that recovered remained unconscious for over 60 hours. Convalescence may be very protracted: one of my cases remained in hospital for six and a half months; in that case there was loss of hearing with headache for weeks, and the mental faculties remained impaired for months.

The pathology of the disease appears to be fairly well established, if we accept the authority of STRENNER, NETTER, WEICHENBAUM, and others, according to whom has been demonstrated the presence of the diplococcus pneumonia, and other micro-organisms in the meningeal exudation, and he assumes, therefore, there is little doubt that the meningeal inflammation is due to the presence of those organisms.

The etiology of the disease is still a mystery. That a specific poison exists, the prevalence of the disease as an epidemic implies; but as to the nature and source of the poison, as to the condition under which it is generated and diffused, we have as yet no positive knowledge. The disease has its favorite habitat in prisons and barracks; it appears to attack males more than females; it attacks persons in all conditions and at all periods of life, though its favorite victims appear to be robust males, between the ages of fifteen and thirty; it prevails generally in the cold season; it does not appear to be either infectious or contagious, or to be much influenced by general sanitary conditions. The outbreaks in the Alipore Central Jail were ascribed by the committee, which investigated the disease in 1891 to overcrowding and defective ventilation, but though

The recommendations of the committee were carried out, outbreaks of the disease have occurred every year since, and there has been an increase rather than a decrease in mortality from that cause. The sanitary condition of the Hazaribagh Jail, in which my first cases occurred, differed so far, as I know, in no respect before, during, or in the interval between the outbreaks. There was not even an approach to overcrowding, the capacity of the four wards, in which cases occurred, being few in excess of the numbers actually locked up. The site of the jail is good, being on a plateau, 2,000 feet above sea level, and there are no defects in ventilation. The general health had been remarkably good from the beginning of the year up to the end of April, and we had no death for over seven months out of a daily average population of 188.

Treatment is most unsatisfactory, and that this is so is, I think, not surprising when the nature and extent of the disease are considered. Treatment must be mainly symptomatic, and various drugs have been tried—opium, quinine, bromide, iodides, belladonna, chloral hydrate, mercury and others—but with very scanty success. Blood-letting was largely practised in former days, and is again being resorted to in Germany. ZIEMSEN and others strongly recommend the use of ice bags to the head, neck and back for weeks together, if necessary, and extensive vesication of the head, neck and back has been tried. My patients, as a rule, were treated in a darkened ward, separate from others, most of the medicines above-mentioned were given, and others besides. The diet consisted of milk, sago and soup, generally given by the mouth, and in a few cases by the rectum. The clothing of the sick was constantly changed, personal cleanliness attended to, and thorough disinfection of the wards carried out.

When I wrote the paper I despatched some days ago I had not the report of my Bhagalpur cases before me. There was great delay in sending me those reports, and I wrote the paper without them. The reports have reached me to-day, and I think some of the features of the two cases were so peculiar that I should bring them to the notice of this Congress.

The case that recovered presented the following peculiar features:—

1. There were marked contractions of the left arm and leg and to some extent of the left rectus abdominis on the second day of the disease. The contractions gradually disappeared, that of the leg before that of the arm.

2. The temperature on the second day fell to 95.5° F. in the rectum and 95.4° F. in axilla; temperature taken very carefully by myself, as I doubted the accuracy of that taken by the Hospital Assistant.

3. Pulse on second day fell to 40.

4. Respiration on second day fell to 12 per minute.

5. Suppression of the urine almost complete for 36 hours.

The patient remained in hospital from 26th December 1891 to 27th January 1892.

The patient that died was admitted to hospital about noon on the 6th November 1892, with high fever. I saw him at the time of admission. He made no complaint specially of pains anywhere. Soon after admission he vomited two or three times and became unconscious about

4 P.M.; same day about 7-30 P.M. both hands and arms became contracted, and he was unable to swallow and continued unconscious. The next morning (7th) I found paralysis of motion complete and of sensation nearly as of right leg; left leg normal, dilatation to some extent of both pupils, which, however, were sensitive to light, lockjaw, contraction of both forearms on arms, fingers normal. The patient could be roused somewhat to consciousness, and he was able to swallow and sometimes to open his mouth just a little. With his left hands he continued, as a rule, to grasp his penis, and when the hand was taken away, it returned to the penis. The temperature in his right hock was 97.6° F., left hock 98.3° F., axilla 99.6° F. (temperature taken by myself), pulse 104, respiration 20. At 3-30 P.M. same day temperature rose to 103.2°. Next morning (8th) temperature down again to 99.6°, contraction of elbow joint diminished, sensation returned to right leg, and there was only partial paralysis of motion, hearing fair, jaws still fixed, but patient could swallow; pulse 100, respirations 20.

Temperature at 4 P.M. 101.8°. Condition otherwise improved; patient able to speak and to drink easily; contractions of elbow joints gone.

9th December. — Morning temperature 102.4°, pulse 112, complained of pain over heart, but no signs of pericarditis, right leg still partially paralysed, tongue very much furrowed.

From 10th to 21st December, when patient died on 16th day of the disease, temperature irregular, ranging from 98.8° F. to 103.2° F.

On 12th December he had difficulty in articulation: pupils noted as normal on that date.

On 13th December he had severe abdominal pain.

On 19th December vomiting of black blood and mucus: hiccup in the evening, gone next morning to return again in the evening.

There was no retraction of the head and no opisthotonos and no eruption; much complaint at one time of pain in spine between the scapulae.

Post-mortem examination showed following marked appearances:—

A layer of yellow lymph along base of brain from medulla oblongata to a point a little in front of optic commissure.

A line of lymph along the anterior and inferior borders of lateral lobes of cerebellum.

A layer of lymph on posterior aspect of cerebellum close to fissure.

A point of purulent infiltration, $\frac{3}{4}$ inch long $\frac{3}{4}$ inch broad, filling up sulcus on frontal lobe, close to longitudinal fissure and two inches behind anterior border. Distension of both lateral ventricles, of one especially with somewhat purulent fluid. Cerebro-spinal fluid in excess.

Brain itself apparently healthy; spinal cord in upper cervical region completely surrounded by a layer of yellow lymph; posterior aspect of cord right down to corda-equina covered with lymph; considerable quantity of serous fluid in lumbar region.

No pericardial effusion, no disease of lungs.

THE MACRO-PATHOLOGY OF CONSTITUTIONAL MALARIA WITH SPECIAL REFERENCE TO ITS TREATMENT BY ALKALINE SALINE MINERAL WATERS.*

BY, SURGN.-MAJOR L. T. YOUNG, M.D., I.M.S.,
Civil Surgeon, Umballa.

ENGLISH text-books of medicine are uniformly unkindly cart, unsatisfying and often misleading on the subject of the constitutional effects of malaria.

These books form either in the original, or as translations, the universal guides to a systematic knowledge of malaria for Indian medical students.

The present appears to me a fitting opportunity for collating, comparing and crystallising out the crude impressions we have one and all acquired in the course of our practice or study in this country.

If this representative meeting gives expression to its impressions of the constitutional effects of malaria and the methods of averting or removing them, it might possibly lead to clearer and more precise accounts of this subject finding their way into both English and American text-books of medicine. The French, Italians and Austrians have a knowledge of malaria far superior to ours.

The subject is an important one, both to ourselves and to the State. To ourselves, because we are all certain sooner or later to suffer more or less from malaria; to the State, because fever alone causes more death and invaliding than cholera, small-pox, dysentery, &c., do collectively.

I venture to lay before you the following generalisations and facts, and invite you to suggest others and to discuss and reject any which seem to you inaccurate or incomplete.

At the same time, I would remind you that malaria differs in its effects in the different climates of this vast empire, and that different observers have had diverse opportunities of noting clinical and pathological facts, or may have utilised these opportunities differently. My experience and conclusions have been drawn from the dry Punjab, alternately very hot and very cold as the seasons change. The first point to which I would direct attention is that—

The treatment of malarial fever should be divided into two stages—

(a) *Curing the attack* by temporarily killing the malarial organism; and

(b) *Removing the condition of the abdominal organs and mucous membranes induced by it.*

This latter is often the more important of the two, and enables the *vis medicatrix naturæ* to throw off the disease better than anti-malarial remedies would enable us to do.

Before discussing the use of alkaline salines in the treatment of malaria, it will be necessary to very briefly consider the pathological conditions produced by malaria and their functional effects.

Even a rather casual inspection of numerous autopsies will, I think, lead to the adoption of the opinion that malaria congests the internal abdominal organs and causes catarrh of the mucous membranes.

A proper recognition of these two facts and their results may be considered the key to the successful treatment of the constitutional effects of malaria.

A.—Malaria congests the internal organs—

(1). *Liver.*—Is it not rare, at an Indian autopsy, to find a liver free from congestion of some form or other? In many the appearances are distinctly those of incipient "nutmeg" congestion, whilst in advanced malarial cases there is distinct cirrhosis of a hypertrophic kind—following to some extent as the result of long-standing congestion, according to the well-known pathological law.

This cirrhosis is not the ordinary "hob-nailed," contracted-surface form, but the enlarged, hypertrophic morocco-leather surfaced, which commences in and around the bile ducts, and which, I venture to suggest, begins as a catarrh of these channels in a manner similar to that in which catarrhal malarial enteritis supervenes on tropical intestinal catarrh.

Tropical hepatic congestion is always associated with more or less fatty infiltration of the liver cells.

Results.—The acute result comprise hepatitis, abscess, perihepatitis, dysentery, catarrh of the ducts, &c. The chronic embrace the various forms of imperfect proteid metabolism or liver indigestion, also gout, rheumatism and possibly diabetes, &c.

(2). *Spleen.*—The early congested and the late cirrhotic stages are only too well known.

Results.—The organ or its capsule sometimes inflamed; the enlargement of the organ may reach an enormous size sufficient to fill the entire abdomen, almost. In the later stages ascites supervenes, anemia and debility with a tendency to sudden death from pulmonary thrombosis as so ably described by Sir JOSEPH FAYRER.

(3). *Kidneys.*—These are nearly always found congested, often intensely so. Of the later stages, the large white has been the most frequent result of my own observations, not the cirrhotic form as one would have expected.

Acute desquamative nephritis is not a rare complication of severe malarial fevers, and it often, in the slighter degrees, is overlooked, and gradually assumes the fatal chronic form.

The dietetic errors to which Anglo-Indians, as a class, are so much addicted, are also largely to blame for many cases of Bright's disease.

Two or even three large meat-meals daily, with many richly seasoned courses, mostly flavored with sauces and vinegar, both so injurious to the prevalent tropical intestinal catarrh, are, as a rule, indulged in. Consider these acted on by—(1) a weak and imperfect gastric juice secreted by a dilated stomach, the glands of which are atonic, atrophied or catarrhal; (2) the imperfect bile secreted by a chronically congested liver. Consider that even this gastric juice has been diluted out of all semblance of even its feeble original digestive activity, by copious draughts of tea or of whiskey and soda, drunk during meals.

It is little to be wondered at if persons, whose digestion is conducted under these conditions, are likely to ultimately suffer from renal mischief.

This result is further contributed to by the lives of hard work, Anglo-Indians lead out here. The idea that

* Being a paper read before the Indian Medical Congress and sent to the *Record* for publication.

India is a country of ease and plenty has long since exploded. It takes as hard, if not harder, work to succeed in life out here as it does in Europe.

Many find themselves, when sadly in need of sick leave to Europe or the hills, unable to afford it. They struggle on for a few years longer and break down or die in doing so. Few can now buoy up their sinking energies by looking forward to retiring with a competence, much less with wealth.

The conditions of existence in the tropics are yearly becoming harder, less elastic, more discouraging. This cannot fail to react upon the general health and constitution of tropical residents. My own impression of these altered conditions of life in India is that the kidneys now break down oftener than previously. Another factor in producing renal disease is the continued elimination by them of the irritating products of imperfect proteid metabolism. This latter is a common result of constitutional malaria and of cirrhosis. In an advanced case of tropical cirrhosis the ureometer shewed only 0.5 per cent. as the daily excretion of urea.

(4). Chronic liver congestion also acts mechanically in congesting the stomach, bowels, uterus, ovaries, rectum, &c. Hemorrhoids are common. These are often accompanied by a permanently moist condition of the anus with a purulent discharge from it.

The uterus is often found enlarged, softened, displaced, its ligaments relaxed and its interior endometritic. The ovaries become the seat of congestive pains, more marked during the actual attacks of fever.

This condition of the uterus is, in my opinion, a result of the extension of endometritis to the parenchyma of the organ and not a direct result of malarial congestion.

B.—*Malaria causes catarrh of the mucous membranes.*

Tropical residence, from the extreme and rapid differences of temperature to which we are subject, and from the excessive humidity of the air during the rainy season, &c., also contributes to the same result.

All the mucous membranes of the body become sooner or later affected by catarrh from the above causes. Pharyngeal and laryngeal catarrhs are generally the earliest to occur. The latter spreads with great frequency up the Eustachian tube, giving rise to otitis media, which often goes on to suppuration with loss of the membrana tympani and ossicles or to plastic inflammation sealing up the ossicles into the fenestra and so causing deafness.

The Schneiderian membrane shares the same fate, and hyperplasia of it over the turbinated bones is a common result. Slight chronic ophthalmia attacks the conjunctivæ. The lining of the uterus becomes endometritic.

The most important catarrh, however, is that of the stomach and intestines.

Under the influence of repeated "long drinks," large meals and hot weather the stomach becomes dilated. Its glandular structures degenerate and atrophy leading to the secretion of a gastric juice imperfect in quality. You may perhaps have observed that an ague patient, who has had a drink of milk half an hour previously, brings it up perfectly uncoagulated, showing the complete absence of acid from his stomach. The thickly loaded, large,

flabby, indented "tropical tongue" is a frequent sign of tropical gastric catarrh.

The intestinal catarrh often causes not alone obstructive jaundice, but ramifies and extends along the bile passages in its more chronic forms. This, as I have already suggested, may act as the starting point of biliary cirrhosis.

Catarrhal enteritis is a common and extremely fatal consequence of extension of intestinal catarrh to the substance of the intestine from its mucous membrane, and its occurrence is favored by the mechanical obstruction to the return of blood from the chylipoietic viscera, by a chronically congested liver. This enteritis is not an æsthenic form of inflammation accompanied by the exudation of lymph, nor does it usually excite the overlying peritoneum to effusive inflammation.

The bowel usually found pale, thinned and anæmic from malarial atrophy, is, when enteritic, found darkly congested, thickened and its mucous membrane soft, and vividly injected. The peritoneal side of the bowel is also red and injected. Long tracts of the bowel are not affected in this intense manner, but only patches of a foot or two. The spaces between these present all the signs of chronic congestion or of incipient inflammation with signs of vascular dilatation and blood stasis. The congestion is usually most marked about the ileum. There is no trace of any ulceration of Peyer's patches or of the mucous membrane. A case which recently died at the Umballa Hospital of this affection had grass-green motions, just like a child with irritative diarrhoea. The colour of the diarrhoea is mostly either pale or dark. I have not often seen it green in adults.

The general condition of the abdominal organs of a malarial patient resembles to some extent that of an animal which has had its splanchnics cut. In both cases the abdominal viscera became surcharged with blood. After splanchnic section however the congestion is active, and there may be a paralytic secretion of digestive juices. Electric stimulation of the splanchnic area and tight bandaging of the abdomen temporarily correct this condition, when experimentally induced, the former by contracting the arterioles and the latter by mechanically preventing passive congestion.

The adoption of electrical stimulation and tight bandaging of the abdominal organs are found clinically to be very effectual, even though the congestion differs in this case in being partly passive, partly mechanical and venous, and in being accompanied by an atonic lack of secretion instead of by a paralytic flow.

Hot salt baths of a temperature of from about 104°F. of half an hour's duration are also useful in remedying this condition, by withdrawing the blood to the skin, and so giving the internal organs a temporary respite.

Already I have alluded to the occurrence of *thinning and wasting of the small intestines* under the influence of constitutional malaria. This is often accompanied by patchy pigmentary degeneration of the intestinal mucous membrane. The coats of the gut become in advanced cases as thin as a sheet of paper.

Malarial degeneration or atrophy of the heart also occurs in advanced cases. This organ is found pale, thin, small and flabby. The ventricular walls are reduced to about half their normal thickness. The muscular tissue is atrophied and fatty degenerated. Such patients

have a poor circulation; they feel cold greatly, are subject to headaches, giddiness, loss of memory, noises in the ears, nausea, faintness, and dyspnoea. They have a feeble hold on life. I have seen two of them die from an ordinary dose of Epsom salts, and many die from exposure to cold.

Malarial Paralysis.—Severe and long-continued malarial fevers often produce paresis, or paralysis motor or sensory, of both of the lower limbs. This was found to be due to *spinal pachymeningitis*, in one case in which an autopsy was obtained: there was no history or signs of previous syphilis in the case. In the last two months I have seen twelve cases of paralysis of the lower limbs due to malarial fever. In one case compression myelitis had occurred; there was complete loss of control over the sphincters with complete motor and sensory paralysis of the lower limbs. The patient, a girl of 13, sank and died of exhaustion and bedsores.

C.—We next come to the question of *how the above conditions may be ameliorated, removed or prevented by alkaline saline mineral waters.*

Of these the chief are those of Neuenahr, Carlsbad and Marienbad. The first is very mild and is suitable for the weakest and most debilitated cases. The last, Marienbad, is the strongest and is suitable for powerful robust cases only. Carlsbad occupies an intermediate position, and is, on the whole, the most generally suitable of all three.

The composition of all three is practically similar, but their strengths differ as indicated above. The composition of Carlsbad water here given will serve to give a sufficiently definite idea of their nature.

The Carlsbad water contains in every pint 53 grains of solids. These solids are mixture of the sulphate, carbonate and chloride of sodium. It also contains from 12 to 20 cubic inches per pint of carbon dioxide gas. When evaporated to dryness a crystalline residue is obtained, which, from its containing 55 per cent. of water of crystallisation, deliquesces in the tropics and is generally inconvenient and unmanageable.

This salt however, by an ingenious process of dehydration and recarbonation, is converted into a very stable and non-deliquescent, though hygroscopic, compound, exported as the "*powdery Carlsbad Salt.*" In this form it is the most convenient and least expensive for use in the tropics.

The *pulverised or powdery Carlsbad Salt* (pulver-forming) consists of:—

| | | | |
|---------------------|-----|-----|--------|
| Sodic sulphate | ... | ... | 43.25 |
| Sodic bicarbonate | ... | ... | 36.39 |
| Sodic chloride | ... | ... | 16.81 |
| Potassic sulphate | ... | ... | 3.06 |
| Lithium bicarbonate | ... | ... | 0.39 |
| Traces of others | ... | ... | 0.20 |
| Total | ... | ... | 100.00 |

An artificial water made with this salt merely differs from the natural water in having its carbon dioxide gas in a state of combination, whilst in the natural water it is present in the free state. This slight defect can be remedied by adding a little soda water to the water in which you dissolve the salt.

The above analyses show that the main constituents of Carlsbad water are sodic sulphate, sodic carbonate

and sodic chloride—a combination of sodium compounds. Even the aphorism of the older physicians—"ammonia for the lungs, potash for the kidneys, and soda for the liver"—shows us that we must expect the main action of this combination to be on the liver.

I shall nevertheless briefly review the therapeutic actions of these salts and point out their physiological uses.

1. *Sodic sulphate* ($\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$) is a saline hydrogogue cathartic or purgative, which has a special action on the liver, stimulating it to increased action. It stimulates the coats of the stomach and intestines to pour out a thin watery secretion which may amount to diarrhoea when the doses are large. It thus carries away water from the blood vessels of the chylipoietic viscera, and relieves congestions of the liver and spleen by depleting the portal system indirectly. Magnesium sulphate acts in a similar way, but is devoid of the special action on the liver that sodic sulphate has. Strong solutions of both these salts precipitate the globulin derivatives of blood and favor the coagulation of that fluid, so that it is extremely unlikely that either of them, in a mineral water, can have any effect in causing absorption of fibrinous exudations. BRAUN states that the effect of this salt on the intestines is mainly irritative, and that it is little absorbed. It decomposes in the alimentary canal, in part into sulphuretted hydrogen, which acting on the small quantities of iron present in the Carlsbad water is said to blacken the feces, and into sodic sulphide.

2. *Sodic carbonate* ($\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$) in the dilute form in which it exists in Carlsbad water is a diuretic and mild antacid. It emulsifies fats. On the presence, in it, of soda depends the alkalinity and fluidity of the blood. It exercises a solvent action on the albumen, fibrin and fibrin-factors of that fluid. A strong supposition exists that this solvent action of soda on fibrin is the normal method of change of substance (proteid) (BRAUN). Clinical experience shows that long-continued administration of this salt depresses, thins and weakens the patient. Excess of soda leads to excessive tissue and other changes. It can dissolve recent inflammatory fibrinous exudations. It is the principal salt in the pancreatic juice of man, and that on which its alkalinity depends. It is the alkali and chief inorganic constituent of bile and has a powerful solvent action on thickened bile and biliary concretions. When ingested it dissolves off old and worn-out epithelium from the mucous membranes: hence its great use in catarrhal dyspepsia. The inorganic basis of the fluid portion (serum) of the blood is soda, that of the solid portion (corpuscle) is potash. "Soda is the alkali, the presence of which is most important to the human system." Soda is the fluidifier of the blood.*

3. *Sodic chloride* (NaCl).—In large doses is an emetic, a cholagogue and hydrogogue purgative. In small doses it unquestionably supplies the stomach with material for the manufacture of gastric juice. It aids and stimulates the digestion not alone of nitrogenous but also of starchy foods. It excites rapid absorption and peristalsis. It is always present, in constant proportion, in the fluids and tissues of the human body, and

*Macpherson's Baths and Wells of Europe.

is necessary in the former for the solution of their proteid constituents, more especially of the members of the globulin family. Wherever active cell formation is proceeding, there we find abundant sodic chloride, e.g., in pus, synovia, grey hepatization of the lungs (BRAUN). In fluid exudations not accompanied by cell proliferation we also find it, as in ascitic fluid. With urea, that ultimate product of proteid metabolism, we find it associated so intimately, that many physiological chemists regard them as forming a definite chemical compound. The greater the amount of sodic chloride in the blood, the larger is the amount of urea excreted in the urine. Hence the use of this salt in cases of albuminuria, where the excretion of urea is diminished. The quantity of salt in the blood is maintained at a constant strength, any excess being eliminated in the urine. The body retains no great reserve of salt as it does of glycogen. The osmosis and endosmosis between the blood and tissues is mainly dependent on the presence of sodic chloride. Waters containing salt are therefore indicated (1) to stimulate and increase absorption and nutrition; (2) to increase and complete elimination of effete matters (i.e., proteid metabolism); hence their great use in gout in which the metabolic changes instead of being conducted as far as the formation of urea, stop short at the stage of uric acid; (3) to rouse the vital functions of the liver and stomach; hence salt is the great remedy for atonic dyspepsia (the dose to produce these effects varies from 60 grs. to 300 grs. daily in 60oz. of water); (4), in scrofulous enlargements of glands and scrofulous cachexia, generally, salt waters are unrivalled. Such patients are, however, usually sent to more purely salt springs than Carlsbad, such as Homburg, Weisbaden, Krenznach, Woodhall, &c.

Action of the Carlsbad Water. 1. General.

1. *On the alimentary canal.*—The effect on the alimentary canal may be judged of from that of a bath of the Sprudel water on the skin. This it whitens, smoothens, softens and rejuvenates, making it like that of a young child. The old intestinal epithelium is softened and gradually dissolved away, exposing a newer and healthier layer beneath. A tongue, whose owner has never seen it clean and free from thick fur for years, is found clean and red, even in the morning. The sodic sulphate produces a slight though beneficial irritation and stimulation of the mucous membrane leading to a flow of water from the tissue, and is itself little absorbed, according to BRAUN. This relieves congestion of all the abdominal viscera, more especially of the liver and spleen, reducing them in size. It increases peristalsis, and gentle purgation follows.

2. *On the liver.*—Soda being the great biliary solvent, it eliminates old and thickened bile, and clears the minute bile ducts and vessels. Congestion is relieved. The pathological results of this are: increased functional activity, leading to secretion of bile of better quality, and quantity more perfect and complete digestion of nitrogenous foods (improved proteid metabolism) and removal of the tendency to formation of increased fibrous tissue. Even early deposits of fibrous tissue are said to be removed.

3. *On the mesenteric glands and lacteals.*—Old indurations and thickenings are softened, dissolved and removed—presumably by the sodic carbonate. This permits of free movement of the lymph and chyle. We thus often find that persons remarkable for spare and lean figures, after a Carlsbad course, fill out, become well nourished and plump. The functions of absorption and elimination are improved and invigorated. As result the blood becomes purer and nutrition improves.

4. *Genito-urinary system.*—Urine is copiously evacuated, owing to the increased blood pressure caused by ingestion of the hot water. This carries away effete and harmful materials which had previously been lurking in the system. The urine voided is richer in epithelial debris, and this must be the result of a clearing of the lumen of the urinary tubules and passages. Congestive affections of the ovaries and uterus are relieved—menstruation, which was previously scanty or suppressed, making its appearance in normal amount. Recent inflammatory exudations around the womb, ovaries and peritoneum are said to be dissolved. Those disordered constitutional conditions which lead to the formation of calculi in the kidneys and bladder are removed or ameliorated. The sexual appetite is reduced. For leucorrhoea and other female complaints the injection of the hot Sprudel or artificial water after Emmet's method, produces the best result.

5. *The circulatory system* is stimulated by the warm water, but later on the power of the heart is slightly lowered by the depressing effect of the free alkali. This leads to slight giddiness, nausea, noises in the ears, faintness, slight loss of memory, drowsiness and the usual symptoms of a diminished supply of blood to the brain. The falling off in the heart's power may possibly also be due in part to the diminution in the peripheral resistance caused by the action of the waters in freeing out the portal circulation.

6. *The respiratory system.*—Breathing is always relieved by a diminution of portal congestion and removal of abdominal fat. It is slightly accelerated by drinking the hot water.

7. *Tegumentary system.*—As a result of impaired nutrition, the skin of malarial cases is often hard and dry, and the hair falls out. Carlsbad causes increased action of the skin by the action both of the water and baths—it grows soft and moist, and hair begins to grow again. Irritative skin diseases, such as eczema, are soothed and disappear. Scleroderma is also benefited.

8. *Nervous system.*—The alkali soothes the nervous system, calming it and diminishing reflex action. Neuralgias, being the "prayer of a nerve for healthy blood" as ROMBERG asserts, are often much relieved or cured by the blood purifying effect of the water. After the course is concluded, the operations of the intellect are rendered clearer and quicker owing to the blood having been freed from the stupefying and yet irritating products of imperfect digestion, previously circulating in it.

To concisely sum up: All the organs of the body concerned in the digestion of food, in the elimination of waste products and in the purification of the blood, are brought into a healthy state and do their work more efficiently, congestions are removed, and the results of recent inflammations dissipated.

Method of administering the water.—This description will be confined to the method of using the Carlsbad water.

Patients must be prepared to devote two hours, each morning, to drinking the water in the proper manner. On getting up in the morning a dose of $6\frac{1}{2}$ ounces of the natural or artificial water made from the salts and warmed to a temperature of 120°F . should be slowly sipped as it cools down.

After this a walk of twenty minutes in the open air is taken, and then another $6\frac{1}{2}$ ounce dose; a second walk of twenty minutes, and a third similar dose are next indulged in. This is followed by a walk of one hour, after which the patient can have a simple breakfast consisting of 3 (Indian) eggs, soft boiled, about six ounces of dry toast and a cup of tea or cocoa.

A lunch of plain roast or boiled meat, a simple pudding or stewed fruit, may be given at 1 or 2 P.M.

A cup of afternoon tea at 5 P.M.

Dinner at 8 P.M. of fish, eggs, light pudding or stewed fruit. If the patient does not suffer from the headaches neuralgia, melancholy and ill-temper of imperfect proteid, metabolism, and if his liver is not enlarged, he might be allowed meat at dinner also. This course at Carlsbad or in Europe is kept up for at least twenty-one days. In India I have found it best to continue it eleven days at first, then stop it for from four to seven days, and again resume for ten days. It can be given in the hills all the year round, in the plains in the cold season.

The benefit derived from such a course is not experienced at once, but is manifested a month or two later by a vastly improved state of general health, vigour, and digestion. Patients should be informed not to expect full benefit at once.

The course should not be taken during the hot weather, in the plains, for more than four or seven days.

The course should be started with water not heated above 80°F . *The colder the water the more aperient is its action.* It is desirable that its action should be aperient more specially at the start. The object to be aimed at should be to regulate the dose and temperature of the water so as to produce one liquid motion daily, otherwise deleterious matters are re-absorbed into the system and give rise to headaches, pimples, &c., &c. *The hotter the water the greater its effect upon the blood and constitution.*

Some patients are given an extra dose of the water at 11 A.M. and another on going to bed at night. This latter has a great effect in cleaning the thickly furred "tropical tongue."

Diet.—During the course, the amount of food taken is limited.

The following articles of diet are strictly excluded :—

Fresh fruit, salads, acids, cheese, tinned, dried or smoked fish, butter. Sweets, greasy dishes and strong wines or short drinks are also to be avoided.

Contra-indications to the use of alkaline saline mineral waters :—

The presence of any of the following may be considered as contra-indicating the use of these waters :—

1. Valvular disease of the heart.
2. Degenerative affections of the great blood vessels, e.g., atheroma.

3. Advanced malarial degeneration of the heart.
4. Advanced Bright's disease.
5. Any disease of the brain, spinal cord or nervous system (chorea excepted).
6. Malignant tumours and degenerations.
7. Advanced syphilitic disease. A slight attack of syphilis, from which the patient has recovered, does not prohibit a subsequent course of Carlsbad.

Atony of the stomach is likely to be produced if the water is given too hot, for too long a period, or to very debilitated subjects. The signs of its onset are a failure of the good appetite, which patients, taking Carlsbad properly, always develop, and heart-burn. The remedy for it is to stop the water for a few days and to give a teaspoonful of Homburg salts dissolved in a bottle of soda water every morning instead. When a Carlsbad patient's appetite fails, look out for some complication, such as atony or congestions. The latter are sometimes the result of taking the water too hot.

—:—

THE POSSIBLE ANTAGONISM BETWEEN MALARIA AND PHTHISIS

By ARDESHIR DOSSABHOY COOPER, M.B.C.S., L.R.C.P., D.P.H.

Bombay.

MY object in bringing this subject to notice is to give rise to a discussion on a very important point, and to have, if possible, a definite pronouncement of views about it. The discussion and the elucidation of the question are malaria and phthisis antagonistic? Are both of scientific and practical importance for obvious reasons? My contribution to it is merely mechanical in recording and laying before you the opinions of others. I have nothing, either from personal experience or scientific investigation, to add to your deliberations where I have come more to learn than to speak. There is much need for the above question to be answered and for attempts to be made to investigate and determine the relationship existing between the two. The matter has received at our hands less attention than its importance deserves, and the determining of the fact, if it be a fact, cannot fail to be of practical value. The subject is full of difficulties, and numerous factors of climate, food and racial peculiarities, &c., have to be taken into consideration before a solution can be arrived at, for which purpose no sufficient data are available. However, I trust an attempt may here be made which will, in some future time, bear fruit.

As late as 1811, it was put forth by WELLS that malaria and phthisis were opposed to each other, and he cited many authorities in support of his views. In 1841 HARRISON of Horncastle remarked on and drew the attention of the profession to the infrequency of consumption in the fens. These views were revived by M. BROUQUE in 1856, who held that malaria and phthisis were opposed to each other. He formulated his views under three heads: (a) that where malarial endemic fevers are prevalent, phthisis is rare, and that the frequency of one class of cases is inversely proportionate to that of the other:

(b) that where malaria decreases phthisis increases; and (c) that phthisis is more curable in malarious regions than in others." Writing on this subject the late Dr. PEACOCK instances six cases, in which phthiisical patients under his treatment were suffering from ague, thus leading him to reject the idea of there being any material antagonism between the two maladies, but he is careful to add that "the facts do not, however, warrant the denial of the supposition altogether, and there are probably few popular ideas which have not some foundation in truth."

Dr. PETER GOWAN, formerly in the service of the King of Siam, does not believe in this supposed antagonism as he has observed ague and phthisis prevailing in the country. He also is careful to admit that "it has unquestionably been shewn to be almost, if not quite, absent from many such localities and to be less prevalent where the fever was of a bad or obstinate kind."

Phthisis is hardly ever seen in Corea, although malarial fevers, which go by the name of "Hakuchu" are common enough.

It has been observed by the great Professor VIRCHOW, that fever prevailed to a frightful extent in Silesia, where nearly every one had enlarged spleen (although the medico-legal importance of the fact does not seem to have been sufficiently realised by the inhabitants). Professor VIRCHOW hardly ever saw a case of phthisis, and he was borne out in this observation by all the medical practitioners in that country. Dr. HUNTER, late Colonial Surgeon to British Honduras, says that "phthisis does not seem to originate in any degree in the Colony, but very frequently cases of this disease are sent to our public hospital from some neighbouring state. Some instances of this affection seem to derive the greatest benefit from a stay in the Colony—all the more violent symptoms subside, strength is regained and a life, that in other countries would have been of short duration, has been prolonged, and a good old age arrived at." The capital town of the Colony is surrounded by swamps and thick jungle where fevers are frequent, although not of very severe type. In 1890, sixty-nine cases of intermittent fever, with two deaths, were treated in the hospital. This by no means represents the number of cases occurring. They must have been very numerous but not sufficiently serious for hospital treatment.

Numerous American observers, as Dr. GREEN and others, advance views supporting the antagonism. Dr. GREEN had remarked that not a single case of phthisis was to be seen in his district where paludal fevers were very common, and he observes that phthiisical patients coming to the locality were much benefited and found "relief as decided as it was permanent". He mentions an instance in which a morass near Rutland was converted into a pool when fevers were replaced by phthisis, and on the reconversion of the pool into morass intermittent fevers re-appeared.

A French author, M. JORDANET, in a book published in 1861, mentions two provinces: Yucatan and Tabasco. In Tabasco fevers are very common and phthisis rare, whereas in Yucatan it is the other way about, and the fact is so well known and appreciated that persons suffering from phthisis are ordered to Tabasco by medical advisers.

I will now take you over the experiences of Dr. R. W. FELKIN, Lecturer on the Diseases of the Tropics in the Edin-

burgh School of Medicine, in his travels through Central Africa, where he had exceptional and varied opportunities of observing the prevalence of malaria and phthisis. He seems to have come across very few cases of phthisis, and even these corresponded in a very remarkable manner with the absence of malaria. In the swampy districts of Unyoro and Uganda he met with but few cases of phthisis. The same is his experience in his journey from Khartoum to the Albert Lake along the Valley of the Nile. However, while returning, he saw a large number of cases in the district of Shufi at an altitude of 8,000 to 4,000 feet, where malaria is rare. Of imported phthisis he met numerous cases in the Ghazal District, where they had come from the elevated regions of Mombutu. Again in the highlands of Gebelmarah region phthisis was observed to prevail extensively and ague was quite unknown. Dr. FELKIN mentions several cases of consumption benefited and even completely cured by a sojourn in malarious districts, although he is careful enough to take into account the element of coincidence or accident in the matter.

It will be not uninteresting to notice to a certain extent the geographical distribution of the diseases. In Siam phthisis and malaria are both common. In Corea, as already mentioned, ague is common; though the country is dry, with very few marshes and swamps, phthisis is quite unknown. In Japan, ague is rare and phthisis not very frequent. Southern provinces of China are very malarious, but it is not known whether phthisis is rare or otherwise. Paludal fevers are very rife in Burmah, and I hope some light will be thrown by medical men from the provinces as to the prevalence of phthisis. Phthisis is very infrequent in Senegal, Benguela, Angola and East Indies, malaria being common. Australia, Tasmania and New Zealand are free from paludal affection, but yield a very heavy death-rate from phthisis. Phthisis is very frequent in Nubia, Chilli and Lama, and almost unknown in Egypt, Syria, Algiers and the steppes of the Kirghiz. From these facts we cannot help feeling that neither temperature, atmospheric moisture, nor geographical position explain this. Dr. FELKIN wrote to Dr. HAVILLAND, distinguished for his researches into the geographical distribution of disease in England, for information respecting this subject, and I will venture to transcribe an abstract from his letter to Dr. FELKIN. He writes: "Lincolnshire has a low mortality from phthisis among females, and forms an exception to the general rule which at present seems hidden in obscurity. We must, however, remember that ague is prevalent in this part of England, and it is said that this disease is seldom associated with consumption. A more important coincident fact is the one that a greater portion of this land is reclaimed from the sea. It is well known that many sites, although damp with sea water, enjoy a remarkably low mortality from phthisis. Again, if you look along the once ague-districts, the North Coast of Kent, you will see the whole length of it characterised by a low mortality from phthisis among females, although much exposed to strong winds. So far then as I can see from the few instances quoted, there appears to be no marked increase of phthisis in the districts named as once characterised by ague, but it does appear that in

such localities phthisis is less prevalent than in other districts, although these may be exposed to the full force of the strong winds found to be so fatal to the consumptive elsewhere. This involves the question: Are there as many consumptives to kill in these malarious localities, and if there are not, why not?"

Racial peculiarities for these diseases would no doubt be very interesting, and could not fail to throw considerable light on the solution of this matter had we reliable and numerous data to work upon. Unfortunately we do not stand at present in a position to speak with any degree of authority or weight on the point. Besides, the racial question is so very intimately mixed up with the climatic food and social considerations, that it seems at present well nigh impossible to separate one from the other in order to determine with accuracy the part played by each. I will, however, venture to put before you the following fragments of information collected from certain portions of the United States which are now the mixing ground of various races, and where practically identical circumstances of food and climate prevail. Colored races are more liable to tuberculosis and pneumonia and less liable to malaria and yellow-fever than the white. Jews are said to have the highest vitality and the least mortality, being remarkably free from phthisis. The Irish race is peculiarly prone to tubercle of the lungs. Aboriginal Indians are being decimated by phthisis, which was quite unknown amongst them. These bits of vital statistics are given for what they are worth. They do not throw much light on the subject, and are given here to direct your attention to the discussion of the question of racial peculiarity.

You must have noticed, gentlemen, that no mention whatever has been made of India throughout this paper where both diseases are found existing. I will leave it to you to give benefit of your experience one to another from different parts of this great continent, and to determine whether malarious parts of it are absolutely or comparatively free from phthisis, and whether the malarious localities are more favorable residences for phthisical patients. The determining of these questions is beset with many difficulties, not the least important of which are imported cases of phthisis in a district which is so easy and common in these days of easy and rapid travelling. If I can venture to suggest, I should ask you for various reasons to ignore altogether the data gathered from the metropolitan cities and large towns where population is more or less fluctuating and rely mainly on statistics gathered from rural districts where the population is more stationary.

THE USE OF NARCOTICS AND STIMULANTS AND THEIR EFFECTS ON THE HUMAN CONSTITUTION.

BY RAI KANNAI LAL DEY, BAHADOOR, C.I.E., F.C.S.
Late Chemical Examiner to the Government of Bengal.
(Continued from Vol. IX., page 173.)

OPIMUM occupies an important place, and though comparatively more costly than most inebriating agents; it makes up by a very small quantity being sufficient for all purposes either of intoxication or of medicine.

Turkish Opium.

Since Müller made the above analysis five other constituents have been discovered, which are thebaine, opianine, pseudo-morphine, porphyroxine and papaverine. It is the proportion of morphia existing in any variety of the drug which determines its value, and in this respect Indian opium is inferior to the Turkish, but in the markets, where it is valued, it has no competition.

As far as is known, its use is confined to three forms: solid pills, smoke or vapour, and laudanum. We owe the introduction of the last into this country to European physicians, and the use in this form is chiefly confined to medical purposes.

The *chundoo* of India is an imitation of the Chinese invention, but *gooly* is wholly Bengalee, having originated in Chandernagore, where it was first used. *Chundoo* is opium divested of impurities such as vegetable matter, resin, and oil with the extractive matter. The soft part of the opium is scooped out of the balls and thrown into an earthen dish—the operative always moistens and washes his hands in a vessel where the water is preserved. When the soft part is carefully abstracted the shells or husks are broken up and thrown into the vessel containing the water. These husks are then boiled in large shallow irons to dissolve out the opium. This boiled matter is strained through folds of China paper laid in a frame of basket work, and over the paper is placed a cloth. This strained fluid is mixed with the soft opium scooped out, and boiled, in another large iron vessel, to the consistence of thickish treacle. The refuse from the straining of the boiled husks is again boiled in water, filtered through paper, and the filtered fluid added to the mass first obtained. The dissolved opium, being reduced to the consistence of treacle, is seethed over a fire of charcoal of a strong and steady but not fierce temperature, during which time it is most carefully worked, then spread out, then worked up again and again by the workman so as to expel the water and at the same time avoid burning it. When it is brought to the proper consistency, it is divided into half a dozen lots, each of which is spread like a plaster on an early flat iron pot to the depth of from half to three quarters of an inch, and then scored in all directions to allow the heat to be applied equally to every part. One pot after another is then placed over the fire, turned rapidly round, then reversed, so as to expose the opium itself to the full heat of the red fire. This is repeated three times:—the time requisite and the proper heat are judged by the workman, from the effluvia and colour. The fired opium is dissolved in a large quantity of water and boiled in copper vessels till it is reduced to the consistence of the *chundoo* used in the shops. In the *chundoo* shops of Calcutta the drug is

smoked by the consumers in the shops themselves, where there are beds, for the smokers, the quality of which varies according to the fee, which ranges from 8 annas to 2 rupees,—a common mat being for the first and a mattress and a pillow on a charpoy are provided for the last or the highest class. It is said that beds become absolutely necessary from the fact that the smokers, fall flat either on their faces or on their backs after inhaling the smoke to their fill, and remain in a trance for hours together, after which they are roused, and both beds and their occupants require to be thoroughly washed and cleansed for the sake of decency. These shops are kept by Chinamen, and are principally resorted to by the Chinese and Mahomedans but scarcely by any Bengalees. Gooly has none of these effects, neither is so much preparation required for its indulgence. Judging from its price, it must be a mixed drug composed of all sorts of impurities which are melted and made into pills. One important ingredient which gives these pills their peculiar character and effect are chips, called *junkoo*, of guava or betel leaves and sometimes of rose petals broiled on a dry pan. For this purpose every shop is furnished with one or two portable forges and bellows. The hooka of the smoker and its pipe are in the peculiar phraseology of the votaries, called *lore* and *jore* respectively. The kulka, *maroo*, in which the pills are dressed for burning, is the stump of what is used for tobacco smoking, being merely the tubular part without the surmounting cup. The fire for burning is made by igniting short sticks of the same materials with which ticea and hooka *gools* are made. These sticks are called *batty*. The tongs with which these sticks are ignited are called *futty luty*, and the chums who meet together in the shops for the purpose of smoking address each other by the name of *i-yarro* or friend. It is indispensable that immediately after the indulgences, the smoker, should have some edible by his side to improve his taste. For this purpose he always provides himself with a cup of sherbet or some bits of sugarcane or sweets. There are many with whom even this simple arrangement is an inconvenience. For them small bits of common cork are soaked in sherbet and they suck one or two of these corks at a time. One or two pice often suffice to purchase as much gooly as is necessary for one indulgence.

Whatever his rank of life may be, a gooly-smoker, is an ugly beast, of a lean haggard appearance, with sunken eyes blackened all round, and a protuberant belly, while the bones of the whole frame seem staring you in the face. An opium-smoker may be distinguished by his black eyes, blackened lips, and thick voice.

Dr. Christison, the most impartial writer on this subject, who always condemns this and other similar drugs, says that its common effect is to remove torpor and sluggishness and to make the opium-consumer temporarily an active and conversable man. Another writer, speaking from personal experience, and comparing opium with wine, thus concludes his observations: "Wine robs a man of his self-possession, opium greatly invigorates it; wine unsettles and clouds the judgment and gives a preternatural brightness and a vivid exaltation to the concepts and admirations, the loves and hatred of the drinkers: opium, on the contrary, com-

municates serenity and equipoise to all the faculties, active or passive; and with respect to the temper and moral feelings in general, it gives simply that sort of vital warmth which is approved by the judgment and which would probably always accompany a bodily constitution of primeval or antediluvian health. To sum up, a man, who is inebriated or tending to inebriation, is and feels that he is in a condition which calls into supremacy the merely human—too often the brutal—part of his nature; but the opium-eater feels that the diviner part of nature is paramount, that is, the moral affections are in a state of cloudless serenity, and over all is the great majestic light of the intellect." Dr. Eatwell, for many years in this country, thus records his opinion:—"The question to be determined is not what are the effects of opium used in excess, but what are its effects on the moral and physical constitution of the mass of individuals who use it habitually and in moderation, either as a stimulant to maintain the frame under fatigue, or as a restorative and sedative after labor, bodily or mental. Having passed three years in China, I can affirm, thus far, that the effects of the abuse of the drug do not very frequently come under observation, and that when cases do occur, the habit is frequently found to have been induced by the presence of painful chronic disease, to escape from the sufferings of which the patient has fled to this resource. That this is not always the case, however, I am perfectly ready to admit; and there are doubtless many who indulge in the habit to a pernicious extent, led by the same morbid influences which induce men to become drunkards, in even the most civilized countries, but these do not, at all events, come before the public eye. As regards the effects of the habitual use of the drug on the mass of the people, I must affirm that no injurious results are visible. The people generally are muscular and a well framed race, the laboring portion of whom are capable of great and prolonged exertion under a fierce sun in an unhealthy climate. Their disposition is cheerful and peaceable, and quarrels and brawls are rarely heard of, even amongst the lower orders whilst in general intelligence they rank deservedly high amongst orientals. I conclude, therefore, with observing that the proofs are still wanting to show that the moderate use of opium produces more pernicious effects upon the constitution than the moderate use of spirituous liquors whilst at the same time it is certain that the consequences of the abuse of the former are less appalling in their effects upon their victims and less disastrous to society at large than the consequences of the abuse of the latter. All authorities seem to agree in maintaining that, when opium is moderately taken, the toxic results are:—the mind is exhilarated, the ideas flow more quickly, and a pleasurable or comfortable condition of the whole system is experienced, which it is difficult to describe. Again, opium is said to possess "a wonderful power of sustaining the strength, which is not found in alcoholic drinks, and of enabling men to undergo fatigue and continued exertion under which they would otherwise inevitably sink."

In the literary ranks of England, Samuel Taylor, Coleridge and De Quincey who were slaves to opium have both of them left remarkable memoirs of their impressions of the effects of opium. The latter who was

an intense pleasure of the drug thus describes the effects of his first dose of laudanum. "But I took it, and in an hour, oh heavens! what a revolution, what an upheaving from its lowest depths of the inner spirits; what an apocalypse of the world within me! That my pain had vanished was a trifle in my eyes. The negative effect was swallowed up in the immensity of those positive effects which had opened before me in the abyss of divine enjoyment thus suddenly revealed. Here was a panacea for all human woes! here was the secret of happiness about which philosophers had disputed for so many ages—at once discovered. Happiness might now be bought for a penny and carried in the waistcoat pocket, portable ecstasies might be had corked up in a pint bottle, and peace of mind could be sent down in gallons by the mail coach." Coleridge was in gloom and despondence while under the influence of the habitant thus paints his misery: "Conceive a poor miserable wretch who for many years has been attempting to beat off pain by constant recurrence to a vice that reproduces it; conceive a spirit in hell employed in tracing out for others the road to that heaven from which his crimes exclude him; in short conceive whatever is most wretched, helpless and hopeless, and you will form as tolerable a notion of any condition as it is possible for a good man to have."

Whatever might be said in praise by the admirers of the drug, my experience is not favourable as take the following picture of an opium-eater: "A total attenuation of body, withered yellow countenance, lame gait, bending of the spine, frequently to such a degree as to assume a circular form, and glossy deep sunken eyes, the digestive organs are disturbed in the highest degree; the sufferer eats scarcely anything and has hardly one evacuation a week. His mental and bodily powers are destroyed, he is impotent."

Opium is largely used in this country in cases of chronic bowel complaints, to mitigate suffering and I know one instance of the energy and liveliness which it is said to impart to the consumer. There was a clerk in a flourishing mercantile firm of this city, who was often made to taste opium, as he was a good judge of the quality of this drug of which he had a daily allowance, which he took during office hours. As long as he had it not he was sluggish, drowsy and perpetually yawning over his work; but almost immediately after swallowing his usual modicum, he would be a changed man altogether, resuming his seat and working from 12 noon to nearly an hour after candle-light, he did the work of nearly four men. He was as quick as he was accurate.

It is a common error that opium induces sleep. It brings on a state of half-dreaming drowsiness; an opium-eater scarcely knows what sound sleep is. That state of listless inactivity which opium produces should not be confounded with sleep. On one occasion, an opium-eater, while dozing on a couch at candle-light, called the servant to replenish his *chillum* with tobacco; and held out his hand for it. The *chillum* was replenished, but the outstretched hand with the hook in its grasp remained stiff and motionless; the man dozed on, the night wore out and nearly an hour after day-light he roused himself and, unconscious that his order of the previous evening had already been obeyed, and that the whole night had passed away, repeated his order for tobacco.

It is remarkable that opium-eaters of this country are inordinately fond of tobacco, which you cannot give them too often. Except that it is an aid to the effects of opium, we cannot account, by any other way, for this inscrutable relationship. Milk, it is well known, is considered as an indispensable adjunct to the opium-eater, who sustains himself by frequent potations of this beverage; and his health and vigor will be in proportion to the consumption of milk.

When once ripened, the opium habit cannot be shaken off and takes such a hold of its victim as to make a slave of him. It is not every man who can be a DeQuincey or a Coleridge; and the following confession of an opium smoker proves how difficult it is for ordinary men to break their opium fetters—"If the usual time of smoking should be put off through any excuse or difficulty, terrible spasms of the muscular system come on, so much so, that I was once lying on a couch which was shorter than my length of body, and something had delayed my morning smoke, when a spasm came on and very nearly dislocated my jaw; another caused my feet to stretch out full against the side of the couch which was broken by the stretch."

Laying aside the question of wholly shaking off the habit, the opium-eater, if deprived of the supply at the appointed hour of indulgence, feels as if he is under the pangs of death. Opium, is supposed, to be consumed by nearly four hundred billions of the human race.

A MIRROR OF PRACTICE.

STRYCHNINE INJECTION IN SNAKE-BITE.

By D. NARAYANA RAO, C.M.S.

Yamethin, Burma.

At about 7 p.m. on the 14th August 1895, a Chetty boy of 12 years of age, while crossing the threshold of his kitchen, was bitten by a snake which also coiled its tail round his leg. The boy cried for help and kicked off the snake which immediately disappeared and could not be found, though closely hunted for. On examining the foot the boy's father found blood oozing from 3 punctures on the dorsum of the right foot. The boy was borne away to a *phoongyi chawng* (a place where Burman priests reside) for treatment; but as they could do him no good, though several of them tried hard all night, he was, as a last resource, brought to the hospital at 8.55 A.M. on the 15th August 1895.—14 hours after the snake-bite.

At this time he was quite unconscious, eyes closed, pupils widely dilated, foaming at the mouth, general features of the face pinched, pulse weak and almost imperceptible, muscles of the body in general relaxed, breathing stertorous. His right foot was swollen. Slight swelling was also observed on the lower 3rd of his right leg. There were three punctures on the dorsum of the right foot (about 3 inch below the right ankle-joint).

Though I at first lost courage on seeing the hopeless case, as I had never come across a case of snake-bite nor seen one treated; but the proverb "While there is life there is hope" encouraged me and I had also read DR. AUGUSTUS MUELLER's memorials dated 6th September, 22nd December 1892 and 10th December 1894, which were

Issued to this hospital by the head of the department. I had gone through these papers more than once when I assisted a confrere writing an explanation as to the cause of death of a snake-bite case under his treatment, but that was his case, not mine.

Though I determined to try Dr. MUELLER's treatment on my case, yet doubts arose on the recollection of the fatal results of the strychnine-injection experiments by Dr. ELLIOT of the Presidency College, Madras. But as I dared not lose much time in thinking over this, I attributed Dr. ELLIOT's failures to his having tried them on lower animals, which, as Dr. MUELLER says, are very apt to be thrown into violent and fatal convulsions. Moreover, while he merely contradicted Dr. MUELLER, Dr. ELLIOT does not suggest a better remedy, so I resolved to try the strychnine injections and leave argument for some other time.

The first injection, 10 minims of the B. P. liquor strychnine, was given at 9 A.M. and repeated every 20 minutes till I gave 5 injections. Half an hour after the fifth injection the patient began to open his eyes, slowly coughed out the froth and phlegm from his mouth, body became warm, patient began to recover from his unconsciousness. I took his temperature. It was 99°F. The pupils, were contracted, yet not perceptibly, and as patient seemed much better, I discontinued the injections.

But at 11-35 A.M. there was a relapse of the signs of snake poison. So I gave six more injections at half-hour intervals till 2-30 P.M., when the patient widely opened his eyes, the pupils still dilated, the body was hot; temperature 101-4°F. muscles of the body getting firmer, consciousness very good, gave two more injections, one at 4 P.M., and the other at 6-10 P.M., half an hour after which the patient's voice returned though not quite natural. Pupils still remained dilated.

From the beginning up to the end the patient was not allowed to sleep and so on till 9 P.M., when I visited him and he desired me to allow him to sleep. His voice was quite natural then. I asked the Civil Surgeon's permission and allowed him to sleep and when I saw him next day at 5-30 A.M., he greeted me with a cheerful good morning.

He is as healthy to-day as he was before being bitten by the snake; and during the course of treatment had taken 130 minims of liquor strychnine B. P., corresponding to 1½ grain of strychnine.

I am very thankful to Dr. AUGUSTUS MUELLER and am so pleased with the results I obtained that I shall always use this drug in snake-bites, as I do quinine in malarial fevers and sulphur in itch, provided the subjects are human beings and not lower creatures.

A CASE OF RENAL COLIC, PASSING OF PHOSPHATIC SAND AND INSTANTANEOUS RELIEF, FROM EXCRUCIATING PAIN, AFTER MORPHIA INJECTION.

By JOHANNES MOTIRAM, C.M.S.

Pandya.

A FAIRLY well built adult, at 40, of sedentary habits, was suddenly taken ill with pain in the right lumbar and iliac regions, radiating downwards along the course

of right ureter. Micturition frequent, only a few drops of urine passing at a time, attended with pain, before and after each act. Bowels rather constive, though moved in the morning. Temperature normal, acid urine, and as he had similar pain about three years ago.

R. Liq. Ammon Acet. ... 3vj
Spt. Aether Nitr. ... 3jss
Pot Citras ... 3j
Tinct. Hyoscyamus ... 3jss
Mag. Sulph. ... 5jj
Aqua Camphora ... 3iv

M. Ft. Mist. † every 3rd hour with plenty of water. Fomentation to the painful part and flannel roller round the abdomen.

The pain having tempered down by 8 P.M. the following was given:—

R. Quinine Sulph. ... gr iiss.
Opium ... gr ss.
Ext. Gentian ... g. s.
Ft. pill i. Give at once.

18th.—Bowels have not moved. Temperature normal. Urine 20 ozs., sp. gr. 1015. Reaction highly acid, albumen †. Frequency of micturition continues. Painless.

Continue mixture omitting Mag. Sulph. Poultice to the part. Warm water enema. The enema returned freely, bringing with it fecal coloured fluid, but no lumps, and at 5 P.M. urine was voided in large quantity; but the pain became excruciating. Patient rolling in bed and crying so for relief, that I administered morphia hydrochloras † grain hypodermically into the lumbar region, and the pain almost instantly passed off. Had a good nap in the afternoon.

20th.—Had sound refreshing sleep for the night. Pain occasionally during micturition, but less in frequency being 5 ozs. at a time with a total of 35 ozs. with an acid reaction sp. gr. 1008, and white deposit at the bottom, dissolving in nitric acid, but imparting a gritty sensation to the fingers, on rubbing, lots of phosphates, no albumen, temperature normal.

Hereafter the progress, of the case was most satisfactory. the urine daily increasing in quantity. No pain during micturition. Urine continuing acid till the 23rd and then neutral till 27th, when the patient went for a change, rendering further examination of urine impossible. Whitish deposit continued increasing for two days and then gradually diminishing. Under microscope a number of quadrangular formed crystals with oblique truncated extremities were detected, at first very dense but lessening till 26th, when only a few crystals were detected. 20th and 21st Mixture was given every fourth hour, and from 22nd to 26th every sixth hour.

And the diet was restricted to milk, only throughout, the treatment.

26th.—R. Liqr. Strych. Hyd. ... m̄ v
Tinct. Gentian Co. ... m̄ xx
Acid Nitric Dil. ... m̄ xv
Aque ... 3i

M. Ft. Mist. to be taken thrice a day, and advised to continue for a fortnight.

I would call especial attention to:—

(1) No gravel noticed throughout, though the urine was carefully preserved.

(3) Presence of, excruciating pain, though only sand passed.

(8) Non-recurrence of pain after morphia injection, though excretion of sand continued increasing.

(4) No rise of temperature, except 99° 8' F. on the 19th, the day of intense pain.

A SUCCESSFUL CASE OF LATERAL LITHOTOMY.

By M. ARATSHUNKER, C. M. S.

Merta Dispensary.

RAMDIN, aged 4 years, was brought to this dispensary from Padu, a village some 14 miles off. As he complained of stone in the bladder of, two years' duration, a sound was passed and stone being detected he was advised rest from the 18th to 24th July, when a dose of castor oil was given him, followed by an enema the next morning.

On 25th instant he was placed in the lithotomy position, chloroform administered, the stone localised by a sound which was replaced by a median staff (No. 4) which an assistant was directed to hold well against the arch of the pubis. An incision made on the left side of perineum, about $\frac{1}{4}$ inch above the anus; was carried downwards and outwards midway between the anus and tuberosity of the ischium for about $\frac{1}{4}$ inch, then it was turned inward till the groove in the staff was felt: when the knife was removed and the left index finger, well oiled, being introduced into the wound (the nail being fixed in the groove) a probe-pointed bistoury was passed along the finger, to direct its point into the groove. The membranous portion of the urethra being opened up by depressing the edge of the knife, the finger was passed into the bladder, directing the parts as it entered, till the stone was felt. When the lithotomy forceps was guided in and the stones caught and removed, one by one. The bladder was washed out with cold water which checked the slight bleeding present, the usual dressings were applied. There were three stones of the size of a supari,³ without facets, and weighing 162, 149 and 104 grains, respectively, or a total of 415 grains.

For the next three days morning temperature remained normal and evening 101° 7' F, but after this there was no fever and quinine sulphate was given. For the first ten days the patient urinated from the wound, for the next fourteen per urethra and wound; after which, the wound healing up, micturition took place per urethra only and he was discharged cured, in exactly a month and six days after the operation.

A CASE OF OPIUM POISONING TREATED WITH PERMANGANATE OF POTASH: RECOVERY.

By L. M. CROWDHURI, L.M.S.

Officiating Civil Surgeon, Balaghat.

THE little daughter, *et.* 10 months, of one of my jail warders was brought to the Police Hospital, because she had been sucking some opium, about an hour previously. It appears that her mother bought a small lump of opium,

worth one anna, and kept it in a small tin box, out of which the baby girl got this lump and commenced sucking it, until she was seen by her mother who at once snatched what was left out of her mouth, and went to the jailor for some native medicine but was advised to go to the Police Hospital at once.

Before I saw the child, the Hospital Assistant had given her an emetic of zinc sulph, but the vomited matter consisted principally of mucus and was quite clean, though slightly smelling of opium. The girl was unconscious but could be roused by pinching. Pupils were pin-pointed and regular. On weighing the remaining quantity of opium I concluded that she must have sucked about 8 or 10 grains; so I gave her, a teaspoonful, every quarter of an hour, of a 2 grain per ounce solution of potassium permanganate; but three hours later the girl becoming quite unconscious, and probably moribund, I ordered her two coffee enemata of $\frac{1}{4}$ an ounce of prepared coffee, at one hour interval, and continued the above permanganate mixture every 15 minutes, for another three hours, when I had satisfaction of finding the child quite conscious and being suckled by her mother. Her pupils were still contracted, but her pulse was fair and she was well, having in all taken only 5 grains of the permanganate of potash.

OBSERVATIONS IN A CASE OF DIABETES MELLITUS.

REPORTED BY DOLATRAI DANYABAI, C. M. S.

West Hospital, Rajkot.

A PATIENT named APA MANGUR was admitted in the West Hospital, Rajkot, on 3rd December 1894, complaining of frequent micturition, excessive thirst and collection of ants about his urine. He was emaciated, skin dry. Urine 94 ozs. in 24 hours, sp. gr. 1010. Sugar present in large quantity. Since admission he was put on milk diet and codea $\frac{1}{2}$ gr. thrice a day.

*Present in large quantity.

Remarks.—Codea accompanied with milk diet reduced the quantity of urine and the sugar disappeared on the 6th day. He diet consisted of the continuance and discontinuance of bread, sugar and fresh vegetables (leaves) on and off.

I am much obliged to Surgeon-Lieutenant Colonel, F. C. BARKER, M.D., F.R.C. S.I., Medical Officer in charge, for kindly permitting me to report this case.

³A tea nut commonly termed *betel nut*.

OUR PICTURE GALLERY.

SIR JOSEPH EWART, M.D., F.R.C.P., F.C.C.

*Deputy Surgeon-General, I.M.S., (retired) and
J.P. for Brighton, Sussex and Cumberland.*

SIR JOSEPH EWART was educated under the Rev. James Horn, Rector of Stapleton, Cumberland, and the Rev. HUGH STUBBS, head master, High School, Carlisle, and subsequently to entering upon a regular course of medical study, he studied theoretical and practical chemistry under Professor PENNY, and surgical and descriptive anatomy under Professor BUCHANAN, Glasgow. In 1850-51 he was enrolled a student at Guy's Hospital, London. He became a member of the Royal College of Surgeons of England, a Licentiate of Midwifery of the Royal College of Surgeons, and Doctor of Medicine of the University of St. Andrews in 1853. In August of which year he was the only successful competitor for the East India Company's Medical Service, and was ordered to Calcutta, where on his arrival on 31st January 1854, he was first attached to the European General Hospital under GEORGE NICHOLSON. He subsequently did military duty with the headquarters of the Bengal Artillery at Dum-Dum, with the 18th N. I. at Barrackpore, and the 40th N. I. at Dinapore. He was Civil Surgeon of Ajmeer from the 14th August 1854 till 5th March 1857, when he was appointed to the medical charge of the Meywar Blue Corps, Kherwarrah, which he held until 15th November 1861, when he was placed on special duty in the arrear office of the Principal Inspector-General of the Medical Department to organise the statistical office, which he left on being appointed, (10th December 1862), Professor of Physiology and Comparative Anatomy in the Medical College, Calcutta.

He was elected a member of the Council of the Asiatic Society on 7th October 1863, and (27th November 1866) was appointed to officiate as Principal of the Calcutta Medical College and Professor of Medicine, and First Physician to the College Hospital, but on Dr. CHEVREUX's return from leave of absence, he reverted to Professorship of Physiology, &c. On 16th January 1868, being the year before he had been elected a Fellow of the Calcutta University, he was elected President of the Bengal Branch of the British Medical Association in 1869, and member of the Bengal Social Science Association, of which he was President for two successive years, and in this capacity he materially helped Miss MARY CARPENTER in her philanthropic endeavours to promote female education in India. The meetings held in the Town Hall were crowded, and the Presidential addresses were attended by H. E. the Viceroy, LORD MAYO; SIR RICHARD TEMPLE, the Lieutenant Governor of Bengal; BISHOP MILNES, SIR JOSEPH FAYRE, and a number of distinguished Europeans and natives.

DR. EWART was appointed Surgeon Superintendent of the European General Hospital, Calcutta, from 1872 to 1876, during which period he also held the following ex-officio appointments:—President of the Faculty of Medicine and Examiner in Medicine in the Calcutta University; Municipal Commissioner and Justice of the Peace for Calcutta; President of the Snake Poison Commis-

sion and Physician to the Mysore princes. He left India on medical certificate on the 10th April 1878, and in 1879 retiring with rank of Deputy-Surgeon-General settled in Brighton.

Besides being for some of the concluding years of his service Editor and Proprietor of the *Indian Annals of Medical Science*, DR. EWART's literary work includes (1) *The Vital Statistics of the European and Native Armies of India* (2) *The Sanitary Condition of Indian Jails*, on the strength of which he was promised the Inspector-Generalship of Gaols, but he respectfully declined; (3) *Catalogue and Classification of the Pathological Preparations in the Calcutta Medical College Museum*, for which he received the warm thanks of his colleagues; (4) *Poisonous Snakes in India*, chiefly intended to enable District Officers to easily recognise them; (5) Joint author of *Report of the Commission on Indian and Australian Snake-poisoning*; (6) Article on *Dysentery* in *Quain's Medical Dictionary*; (7) *Review of the Treatment of Indian Diseases*; (8) *Typhoid and Typhus Fever in the Ajmeer Jail*, where he was the first to identify the existence of typhoid fever among the natives in India; (9) *The Vital Statistics of the Meywar Blue Corps*, which the Director-General of the Medical Department was pleased to call a model report; (10) *Treatment of Dysentery by large doses of Ipecacuanha*; (11) *Phthisis in India*; (12) Two addresses in the transactions of the *Epidemiological Society of London* during two years' presidency of same in 1890-91 and 1891-92, and many papers published in the medical journals and transactions of learned societies.

It was not till 1884 that DR. EWART began to take an interest in local affairs, and ventured to contest St. Nicholas' ward and was returned to the Town Council by an enormous majority. He was made an Alderman in April 1890, and took up a warm interest in municipal work that he was unanimously elected Mayor in three successive years, 91-92, 92-93, 93-94, during the two last of which a complimentary banquet was given in his honor by his fellow townsmen. At the banquet given by the Mayor to his fellow townsmen and others in his first year of office, and at the two banquets given to DR. EWART in the 9th November 1892 and 1893, the toast of "The Mayor" was proposed in felicitous terms by Sir JOSEPH FAYRE, K.C.S.I., F.R.S., a highly esteemed colleague in former days, in arms and medical work. A local contemporary (*Brighton Herald*, May 25th 1895) says:—

"Of the dignity, the unassumingness, the hospitality, and the ready adaptability to circumstances with which DR. EWART went through his three years' Mayoralty little need be said; nor of the amiability, tact, and enthusiasm with which his sister (Miss Grace Ewart) assisted her brother as Mayoress of the borough. This honorable phase of his career is fresh to the memories of the townspeople. It may, however, be well to recall that DR. EWART's period of office witnesses the taking over and extension by the Corporation of Technical Schools and Art Education, the dedication of the clock tower in Preston Park, the opening of Queen's Park, the starting of a Corporation Band, the celebration of the Duke of York's wedding, His Worship's own three brilliant receptions at the Pavilion, the raising of a Sick Relief Fund for Worthing, the collection of large Hospital Saturday Funds, the opening of Cobden Road Baths, the

Yours Very Sincerely
Joseph Swast

opening of the Abattoir, the clearance of some of Brighton's slums, the opening of the Blaker Recreation Ground, the development of the Electric Light undertaking and the lighting of King's Road by electricity, and the division of the town into fourteen wards."

DR. EWART'S public work in Brighton has not been confined to the Corporation only, as for the last eight years he has been an active member of the School Board, and as Deputy Chairman of the School Attendance Committee has persistently advocated the provision of adequate accommodation to meet the increasing number of children on the roll. Four grand and commodious new schools have been built under his hearty sympathy and support; for he has always been a consistent advocate of free education. He is a Trustee and a Founder of the Throat and Ear Hospital, and has rendered distinguished professional and sanitary service to the town. He is senior Consulting Physician to the Royal Alexandra Hospital for sick children. In 1884-85 he was elected President of the Brighton and Sussex Natural History Society. In his first and second mayoralities he was President of the Epidemiological Society of London, but in the third year of his mayoralty, he became President of the Brighton Medico-Chirurgical Society. He is a loyal and genial Freemason, and is now the Master of the Yarrowburgh Lodge, as well as a Governor of every hospital and medical charity in the town. To commemorate his services to Brighton, a full-sized oil painting of DR. EWART, in mayoral robes, by the celebrated artist, MR. WYERHALL, was presented to the Corporation by MR. COUNCILOR WILLETT, J. P., and now occupies a conspicuous position and permanent home in the local art gallery. He was knighted by the Queen at Windsor Castle, on the 18th of July last "in recognition of services rendered to the medical profession and as Mayor of the important Municipality of Brighton," and the announcement of the Queen's recognition of his merit met with a most cordial chorus of approval in his native country of Cumberland and the town of his adoption as well as by the lay and medical press in all parts of the United Kingdom.

The successful career of SIR JOSEPH EWART offers object lessons to every one called upon to make his own way in life, as though provided with a thoroughly good sound education accompanied by diligent, moral, and religious training, directed to entering the ministry of the Presbyterian Church, &c., he replied, when asked what occupation he wished to follow: "That of the medical profession." He was duly apprenticed, according to the usage of the times, imbued with the idea that after he obtained his diplomas in medicine he would have to depend upon himself, and on the completion of the medical curriculum. He was looking around for employment, when he was greatly surprised, one morning, to find on the notice board of his *alma mater* an announcement that an Assistant Surgeoncy in the Hon. East India Company's service was put up for public competition by those students of the institution who were nearing the end of or had just completed the curriculum. DR. EWART strove for, and won the prize, and soon afterwards sailed in the *Colombo* for the metropolis of British India, where he landed without an introduction or a friend beyond the principles of thrift, self-reliance and devotion to work in which he had been reared and trained. The Marquis of Dalhousie, then Governor-General, appointed

him to the Civil Surgeoncy of Ajmeer, whence he was transferred to the charge of Meywar Bheel Corps at Kharwara, just on the eve of the great mutiny, through which his regiment remained loyal and beyond keeping open the communications, for a time, between Calcutta and the Punjab across the Bikaner Desert by means of Sowran camels and sundry scores of the vicinity or approach of the fugitive Tantia Toppe, the unsettlement of a troop of the 1st Bengal Cavalry, and the assassination of the Risaldar Major and his immediate subordinate, there was nothing to unripple the even tenor of our way. His claim for further promotion came unsolicited one fine morning, after the mutiny, when the Commanding Officer was directed to take steps to relieve him in order that he might take up the special duty of putting into shape the arrear statistics of the Medical Department.

These statistics had been pushed on with all practicable expedition, when DR. EWART was offered the chair of Physiology and Comparative Anatomy and Curator of the Medical College Museum, rendered vacant by the death of DR. CROUWER. The chief work, though self-imposed, here was to arrange and so classify a chaotic accumulation of pathological specimens as to facilitate their utilization by students and professors.

In due course higher promotion awaited DR. EWART on the departure of DR. CHEVERS, Principal of the Medical College and First Physician to the College Hospital, on furlough to Europe. He was requested to officiate in these important and responsible appointments. On the return of DR. CHEVERS, he reverted to his permanent appointment, but eventually the *lucrative* post of Surgeon to the European General Hospital and attached Presidency Surgeonship fell vacant, and LORD MAYO offered them to DR. EWART, and he held those appointments until the effects of a serious attack of typhoid fever necessitated for the second time that he should avail himself of sick leave to Europe (1876). Extensions were obtained until 1879, when being unable to resume duty, he was reluctantly compelled to retire, and terminate his labor in India, which had always been congenial, and attractive to him and where he got on well with the natives, with whom he sympathized to the full, and especially did he feel the wrench of being obliged to sever himself from the students who crowded the class room, his colleagues and the many friends who sought his advice in their trials of difficulty and danger. Brighton has quite renewed DR. EWART'S health, and he now looks back in his new career there, probably not yet finished, with unmitigated pleasure and satisfaction. He is not without hope that he may be spared to, at an early date, spend a winter in India, and renew his friendships and acquaintance with those of his students, colleagues and clients who may still, under Providence, remain at their posts of work, duty and honor—and particularly those of all creeds and castes for whom he had some small part, for many years, in laying the foundation on which has been raised a superstructure enabling them as physicians, surgeons, obstetricians or sanitarians to heal the troubles which poor humanity is heir to, to prolong life by constantly applying to practice the principles of the grand science of sanitation to the prevention of mitigable, avoidable and preventible diseases and so to illustrate the truth of the proverb, that "Prevention is better than cure."

THE Indian Medical Record.

1st October, 1895.

MEDICAL STUDENTS—REAL AND UNREAL.

Dr. BOMFORD, the Principal of the Calcutta Medical College, has issued an edict that the ordinary annual Test and Honor Examinations of the College shall in future be compulsory instead of optional and judged by the results of the same, students who show an inaptitude or indifference for medical study, shall be struck off the rolls. In Dr. BOMFORD's own trite and expressive language, the order reads thus: "I am determined to make this College as incompatible as I can for unreal students." We have received numerous letters on this subject, all taking the part of the students as against their professors, and we have seen volumes of abuse levelled at Professor BOMFORD for his action in this matter. We have wondered how it was possible for these disputants to have so allowed their feelings to overcome their better and sounder judgement. Surely it is in the best interests of parents and guardians that in endeavoring to select a suitable profession for their wards, that any mistake in such choice should be discovered at the very threshold of the career upon which they purpose their charges should launch. Even students should commend the foresight and prudence of a rule which conserves mind, body and estate, and prevents a misuse of one or the other. Every medical student in the world knows but too well ere a twelvemonth of his course is experienced, whether the natural bent of his mind has been suitably directed in his youthfully formed decision to become a Doctor of Medicine. And what better evidence of this unnaturalness of selection can we have than the results of the tests that are applied to ascertain the value of his studies. The student who has made a selection harmonious with his mind and his nature will have carried on his studies assiduously and enthusiastically; while, on the other hand, the young man who has mistaken his avocation, and acted in discord with the natural bent of his mental calibre, will be found, when the test is applied, to have frittered away his time, and neglected his books.

Dr. BOMFORD has rightly classified these students into real and unreal, and he does the unreal man a real service by pointing out to him the error of his ways, the unreasonableness of his choice, and the wastefulness and injury to his parents to persist in prosecuting so uncongenial a course of study. We are surprised indeed to find that so many cultured and experienced administrators, as Dr. BOMFORD's predecessors undoubtedly have been—have failed to exercise this kindly and discriminative judgment in the very best interests of the students who were under their care. How many young men, who for years had fondly hoped to slide through the portals of the College by some stroke of luck, and during those years of painful anxiety to their parents, had neglected their studies, wasted their patrimony and were ultimately compelled to give up the task of waiting upon fortune, returning to their homes with the best part of their life fruitlessly spent with nothing but a gloomy prospect of entering at last upon some

new venture to gain a livelihood. Who does not know how the country is overrun with a discontented, worthless class of unqualified medical practitioners, who style themselves failed M. B.'s, or failed L.M.S.'s. To permit an unpromising medical student to continue for a series of years a hopeless and uncongenial line of work in our educational hospitals, is tantamount to criminal neglect of the interests of parents and guardians, of the students themselves and of society at large, while it seriously compromises the reputation of the institution that allows these wretched students to hang on in their hopelessly cheerless course. When they leave the College as failures, they settle down in some part of the country as practitioners, and here they are even worse than failures, for they become an element of danger to society in being imperfectly equipped and professionally unqualified to practice medicine. We reiterate that the motives which actuate this ruling of the Principal of the Medical College are such as will inevitably conduce to the best interests of the students and of the College. We would solemnly urge our young friends who are studying medicine not to be led away by any unkindly feelings towards their professors and teachers. It is quite possible to misconstrue the loftiest of motives and to vilify the best of intentions, but we aver conscientiously that the application of this punitive ruling can only affect such students who would reflect no credit on themselves nor on the College, by remaining on its rolls, when the evidence of their work and worth gave them no moral right to continue in a career that promised nothing but failure and ill success. It is a great mistake to credit the professors with any suggestion that they desire to diminish the number of competitors who enter the ranks of private medical practitioners from the portals of the Calcutta Medical College. It is certainly to their credit if they can turn out as many good men as possible, and this is their sincere desire. It is but natural and logical that acting in defence of their own reputation and in the highest interests of the College, the students and the public, they feel it their duty to approve the action of Professor BOMFORD, the Principal of the College, and to support him in carrying out a reform that must act beneficially on all concerned. It is said that enthusiasm is contagious. So is idleness. Hence as it is demoralising to keep idle, worthless students in any school because of their baneful influence on others, so it is commendable and right to protect the good who desire to work from those whose example can do nothing but harm. By all means let us support any measure which is right in its motives, and we may safely leave the results to time, for right always wins.

ADVICE TO YOUNG PRACTITIONERS.

THE young practitioner has many difficulties to contend against; and one among the many is the rather general belief that he must give himself the luxury of a wife if he hopes to succeed in building up a good practice. Dr. STUART MCGUIRE, of Virginia, in trying to determine the grounds upon which the public objects to employing an unmarried physician, argues that, as the unmarried physician is his own master, his mind not being occupied by

domestic cares, his interest not being divided between work and his family, and not being the possessor of a trusted but often foolish wife to whom his patient's confidences are communicated.—All these, thinks Dr. McGuire, should make the unmarried doctor a more welcome physician than the married one. We have no desire to handicap the unmarried practitioner by setting the public against the state of single-blessedness, which he may choose, or find it necessary to adopt; but we think that Dr. McGuire's arguments, though theoretically sound, are practically defective. Matrimony may not be a stimulus to mental development, nor should married men be regarded as wiser than the single. Matrimony does not increase a man's professional abilities; nor should one marry simply for the sake of getting on in practice. All this we quite concede to Dr. McGuire; but there are considerations, the correctness of which Dr. McGuire not only doubts but denies, which justify the general preference for the married physician. For instance, Dr. McGuire thinks that there is no lack of sympathy on the part of one who has no wife or child of his own. We would be very reluctant to charge any practitioner, married or unmarried, with being wholly unsympathetic; but every pater-familias knows that his sympathy is of a deeper and truer type than that which he felt in his anti-matrimonial days. Dr. McGuire furthermore adds that "until matrimony shall prove itself a moral safeguard, it cannot possibly enter into this question." Of course it would be downright folly and impertinence to impute vice to the unmarried physician and to make morality and matrimony synonymous terms. But surely Dr. McGuire must admit that while society does not regard matrimony as an infallible moral safeguard; it does hold it to be very much a safeguard; and even from these considerations the public is to be pardoned for any preference it may shew for married physicians. We do not think that "the only possible explanation left is one that is more than a reflection on the doctor's morals." We would indeed very much resent this selectiveness of the public for the married physician, if, by so doing, it in any way impeached the morals of any section of the profession; and we do not think that the public means to thus tacitly malign the unmarried physician.

It is not the married or unmarried condition of the physician so much as his youth that affects these cases, and that without any insult being intended or offered to the morals or professional abilities and experience of the young physician. It is an unexplainable delicacy, hard to be overcome, which affects the whole question. There is much to be found to prove the accuracy of these views. For instance, although the young unmarried physician may not be consulted in reference to the ailments of the ladies of a house, he may be an ever welcome and respected visitor and friend of the family, and perhaps even gladly permitted to form a matrimonial alliance in the family. Again, it may be observed, that while a mother has unlimited confidence in the professional abilities and morality of a young married physician, to whose care alone and to none other she would commit her child of tender years, however dangerously ill, she would yet even in minor ailments of a certain class prefer to consult the

hoary headed bachelor physician of whose experience and morals she may know little or nothing. In none of these cases do morals and experience enter into the consideration; or the fact of a physician being married or unmarried influences the patient's action. This nineteenth century civilisation is not so unreasonable and illogical as to gauge morality by years of individual existence; and it moreover admits that, in the medical profession as well as in any other, there are to be found old heads on very young shoulders, and that age moreover does not always bring with it experience. If then the unmarried physician appears to be placed at a disadvantage in practice, it is to some extent due to his being supposed to be not as truly and keenly sympathetic as the physician with a family. It is a common saying that one must be a parent in order that he may fully realise a father or mother's feelings in any family loss or misfortune. This does not impute hard-heartedness or absence of kindly feeling in the rest of mortals; but that circumstances have naturally rendered the feelings of the one class of beings more tender and more easily and readily affected than those of the other class. The bare fact of a physician being unmarried scarcely affects his practice in any other way. The unmarried physician is generally young, and it is his youth and not his unmarried state that stands so much in the way of his employment under certain circumstances, just as the young married physician, as we have shewn, is in similar cases and is therefore not applied to nor consulted, the patients at the same time intending no reflection on the skill or morals of either physician. We cannot, however, take it as proved by Dr. McGuire that as medicine "demands singleness of purpose and undivided devotion" the unmarried must *pari passu* the better doctor. Matrimony does not destroy, in the physician, devotion to his duties and a love for his work; nor is the unmarried physician so free from worldly cares and distractions as to be able to devote all his time and energies to his profession. The possession of a family is often the married physician's stimulus to greater exertion and to the expansion of his energies; while a judiciously chosen helpmate will not only lighten one's labours, but also help him to better bear the worries and disappointments, from various causes, to which the physician is liable.

—:O:—

ARE CHEMICAL EXAMINERS INFALLIBLE?

Our article on Chemical Examiners, in an issue of not very long ago, receives ample justification and confirmation from the following remarks of Counsel for the defence in a case of culpable homicide amounting to murder, which was tried at the last Criminal Sessions held at Madras: When a man's life was at stake, it was very necessary that the greatest care should be exercised. The Chemical Examiner, according to his own admission, had but a small acquaintance with analytical chemistry. While he was in England he had, some ten years ago, attended a few lectures on the subject, but did not conduct an analytical inquiry. This was the first enquiry he conducted, after his appointment to his present office, for the purpose of tracing arsenic. A series of testings

that are really the most easy known in analytical or forensic chemistry. The jury could not, upon the evidence of such a witness, convict the prisoner. With regard to GOOLAB ROY, the assistant to the Chemical Examiner, the learned Counsel urged that he was more or less aware that his superior did not know much about the subject, and they might take it that he did just as he pleased." We take this extract from the *Madras Times*, and make the remark, in passing, that the chemical analysis in this instance was entrusted by the Chemical Examiner to his assistant. We sympathise with any professional man who may be subjected in an open court to the humiliation which such remarks inflict; but we cannot find fault with the learned Counsel in this case. So long as a Commission in the Indian Medical Service is the all important and indispensable requirement for the Government Chemical Examinership with its State-protection against subpernas and cross-examination in the law courts, and in other posts, we must expect to see round men thrust into square holes and *vice versa*: and so long too must Government expect to have reflections cast on its nominations. Given the civil chemical expert and the commissioned medico of "test-tube experience" to select from for such appointments and the office is bound to fall to the latter: the post lies within the preserve mapped out by Government for the Indian Medical Service, and no considerations will sanction this limitation being encroached upon. Can a Government be credited with holding human life as sacred when it commits enquiries affecting the very lives and liberties of such of its subjects, who may have the misfortune of getting mixed up in criminal matters, into the hands of raw recruits in the field of chemical investigation? The case in point is strikingly illustrative of the danger and ridiculousness of these nominations. The Chemical Examiner in question is a Surgeon-Captain of little over eight years' service. His chemical knowledge and experience appear to be nothing more than that obtained in the ordinary course to qualify for a registrable British qualification to practice medicine. We all know that if such knowledge and experience of chemistry cannot be exactly pronounced scant and superficial, it certainly little fits one for the important analytical work demanded of Chemical Examiners to our Governments. The special aptitude (?) of the officers in question for chemical analysis was however detected by the Madras Government some two or three months ago on the permanent incumbent having made up his mind to proceed on furlough. It is wonderful with what facility, and in what a short space of time, our Governments in India are able to hatch and give full feathers to chemical experts, or for the matter of that to any medical professor. The period of incubation, growth, and perfect fledging occupies only as much time as it takes for the sanction of the arrangement, and the passing of the order through the Government press. Three or more sessions will have been held before the permanent incumbent will have returned to his post of Chemical Examiner with the Government of Madras, and goodness only knows how many unfortunate dooms will, by that time, have been irretrievably sealed on the authority of the acting veritable tyro in chemical matters. Would it not be far better to give the acting appointment in a case

such as this to the experienced assistant than to one whom neither experience nor training, but a Government *foet* dangerously presumes to manufacture? If the assistant can acknowledgedly be entrusted with such analytical work, while the inefficient Government Examiner is, endeavouring to gain experience, what necessity or advantage is there to the state, to the law, or to the public in having a nominal figure head, while the work and responsibility of the assistant are increased?

We would draw attention to one other class of appointments which are filled with little or no regard to the training, aptitude, or experience of the incumbents, *viz.*, the superintendence of lunatic asylums in this country. It is not long since we were treated in an important and especial report to a very outspoken expression of opinion on the way in which the asylums are officered. The entire lack of special training in the superintendents was attacked in terms which we are not able to reproduce, but in which, we feel fairly safe in stating, ignorance and such like expressions entered. Mental disorders form one of the regions, of our profession, which is said to have been little explored during the past thirty years and more; and we can scarce hope that, even to the end of time, India will ever be able to contribute any quota of improvement or advance in this direction if her superintendents of lunatic asylums are to be so decidedly unfitted in most instances for their charges; and unfitted we must expect them to be so long as a Netley, course and a place in the Indian Medical Service are the only gates by which men can get to be appointed to the charge of these asylums.

All these ill-advised and unsuitable nominations must be expected to lead to unpalatable, yet just, reflections on the Government, on the nominees, and on the service to which the nominees belong; and they are harmful-furthermore in bringing disrepute on the profession. It may be urged by some that no honest physician should enter upon duties to which he feels he cannot do justice, or which he thinks himself incompetent to discharge; but it is the present condition regulating appointments, and not the service men, that are essentially to be blamed. The men know that the appointments must go to service men, and that the general medical education of the men of their service is much the same; so that one may feel that while he perhaps cannot do much more good in any of these special appointments than another of the service can, he may justly content himself with thinking that he certainly cannot do very much more harm, and that he may, as well as any other, and with no more injustice, hold the appointment that offers, or is offered to him.

It is quite evident that no justice can be done to our calling, or to State interests, or to our people, and that no encouragement can be given to specialism in this country so long as selections for special appointments are made from a limited field and from among a favored few.

—:—

THE BRITISH LAW OF INFANTICIDE.

AFTER carefully wading through all the literature available in Great Britain concerning crimes relating to pregnancy Professor, JOHN GLAISTER, M.D., L.M.C.P.&S., D.P.H., of St. Mungo's College, Glasgow, urges that as the thought is always father to the act and the culpa lies just as much in the commission of, as in the intent to commit,

a crime; there ought to be no difference whether the illegal operation be successful or not when meting out the award for the offence. He pleads strongly that the British law dealing with criminal abortion is in some respects "illogical and inconclusive that it needs instant and considerable amendment; as a premium is offered to crime by the rulings that though any attempt to hasten the expulsion of the product of conception before it reaches maturity and natural delivery constitutes an offence, amenable to criminal law, still any one may, with absolute impunity, murder a child during the process of natural birth, provided an independent witness be present at the killing, and it is not a crime to destroy a child *in utero*, by violence, no matter whether it be quick or not (because though it be quick it is only *pars viscerum matris* and not a separate being under the king's peace) provided that the violence is not accompanied by the consequent premature expulsion of the fetus from its mother's body. But should the fetus survive this violence and after going on to full-term and natural birth then die by reason of the injuries priorly received, the person who caused the violence will be chargeable with the crime of murder. In its present condition the law seems made not with the object of convicting and punishing the child murderers, but of ensuring her acquittal from this serious crime: for *physiological* life begins from the very moment of conception, while *legal* life, except in judicial homicide, matters testamentary and *in possession fratris*, does not begin until it becomes a distinctly self-existent human being, whose entire body has been delivered from its mother by natural birth, and English canonical law considers life not to commence before the infant quickens by being able to stir in its mother's womb. Suppose these facts were generally known, women, instead of covering their disgrace by inducing abortion and thus risking a criminal prosecution, would wait for a few weeks longer till natural delivery was about to take place, when they could cover their shame and escape and defy the rigors of the law by seducing a friend to stand by and smother, or otherwise kill the babe as soon as its head and neck saw the outer world; while the remainder of the body was still *in utero*: for the woman or person who deliberately does an infant to death *during* natural labor, but before it has been wholly born is not guilty of any offence against the law. And all this confusion and failure of justice must exist so long as the law, instead of being concise and definite as to the meaning of the terms "new-born" and "live-birth", raises difficulties by creating differences in their interpretation by the legal and the medical mind. DR. GLAISTER gives several instances where, in its present condition, the law is far too inadequate to meet the ends of humanity and justice by assuming the peculiar attitude of preventing conviction on the charge of infanticide, even though the violence that destroyed the child may be of the most brutal character, because, though he could safely take oath that the child was alive when a portion of its body was born, the medical expert cannot be certain, much more swear, that the *whole* of the infant's body was born before the violence was offered. Medically there is no difference as to whether a child, other than still-born, be wholly or partially born to establish the fact of its being alive at natural birth, and

while the civil law demands that the sign of live-birth be any attempt, no matter how feeble or how imperfect, on the part of the child to breathe, the criminal law, in a manner affords an indigement to crime by defining "new-born" as a child that is "wholly born," i.e. "one whose entire body has been delivered from the body of its mother" and "live-birth" as a child in whom independent existence has been established by the action of its own organs *after complete* delivery and that till delivery be complete a child cannot be considered as a creature in being and under the king's peace. These then, he holds are conditions and anomalies very serious to contemplate and common sense and justice demand that they should no longer exist.

CHRONIC INEBRIETY FROM A MEDICO-LEGAL POINT OF VIEW.

WHILE lecturing before the American Association for the study and cure of inebriety, T. D. CROTHERS, Esq. M.D., urged that as chronic inebriety was common to all classes of society, whether rich or poor, high or low, it behoved all, criminally inclined, who had "drink histories" attached to them to place themselves under the care of some competent doctor before their cases are adjudicated, so as to enable him to determine what disposition should be made of them as they are *not* accountable for crimes committed on the impulse of the moment, while under alcoholic influence.

Dividing chronic inebriates into two classes, the *continuous* and the *periodic* drinkers (The former of whom drink daily and to excess whenever they can procure liquor, and the latter have distinct drink paroxysms which subside, usually, from exhaustion and begin afresh when a degree of restoration comes on) he points out that whether they be of large coarse frame or of small irregular development, the entire bodies of people of the latter class seem to be stamped with signs of imperfection and degeneration and a broken down nervous system.

Arguing strongly in favor of *heredity* as an important factor, he also contends that the continual indulgence of all the impulses and passions in surroundings full of the contagion of bad examples, dangerous insanitary conditions: irregular or unhealthy living, sleeping in insufficiently lighted, or badly ventilated rooms, living on unnutritious food or in a depraved mental atmosphere, all help to promote chronic inebriety, rob a man of every thing pure and noble and leave him a perfect wreck, morally as well as physically. He points out that while chronic inebriates manifest an unusual susceptibility to the personal influence of those persons (particularly to some favorite bar-keeper) who join them in drink, they exhibit an antipathy and even hatred towards anyone who antagonizes their conduct and mode of life. In this feature appears to lie a peculiar hypnotic power which varies widely in force and duration, and is very unstable; for while it may be used for the purpose of crime it cannot be depended on to conceal such crime, as chronic and degenerate inebriates, while susceptible to criminal suggestions, lack the reason and steadiness of purpose necessary to perfect suggestion. The confused brain and rapid

physiological changes rendering fixity of purpose and rationality of action impossible. Each glass of spirits increases the circulation of the blood in the brain for a brief space, but very soon diminishes it. The exhilaration and rapid thinking of one period being so closely followed by the slow, confused thought and heavy depression of another, fixity of idea, sequence of argument and continuity of action become so impossible as to in great measure render criminal suggestions inert or contrary to the plan snapped out. Now as many of the criminal acts of inebriates come from centres of infection and are fatal, unreasoning, largely accidental and of an insane transitory type, he finds that sexual crimes are much more rare than are acts of violence; in that excessive alcoholic indulgence so early exhausts the sexual impulse as to render criminal passion a very small element in criminal acts; and he therefore thinks that the chronic inebriate should be treated as a dangerous lunatic.

COMMENTS AND NEWS.

THE MEDICAL PRACTICE QUESTION IN INDIA.

THE *Indian Planter's Gazette* continues its *exposé* of the official monopoly of medical practice in India, and in its second article on this subject, our esteemed contemporary deals with "THE WORK OF OFFICIAL DOCTORS" as follows:—

"In our last article we endeavoured to prove that however justifiable may have been the necessity 50 years ago of permitting Government doctors to engage in private practice, or to supply the medical needs of the civil population in our large cities, no such need, we also definitely proved, exists in the present day. We proved that numerically there was a sufficient supply of civil or independent physicians to meet all the demands of the European inhabitants of our large cities, as a distinctly European journal we are dealing entirely with European interests as apart from purely native interests. We maintained that neither necessity, nor any other consideration can possibly justify the present state of things, which permits State-paid doctors to enter the field of private enterprise in rivalry with independent physicians, just as though they had no obligations whatever to fulfil towards the Government which pays them handsome salaries for certain well-defined, stipulated duties.

One would naturally ask what is it that Government doctors in our large cities have to do? How is it that they have so much leisure at their disposal? What indeed is it that they receive their handsome salaries for? We will endeavour to answer these questions.

We will take the case of a Surgeon-Lieutenant-Colonel who holds the post of First Surgeon to the Calcutta Medical College Hospital, who is a Professor of the Science and Art of Surgery. Verily it might be said, a doctor who has the responsibility and care of at least 70 patients on his hands daily and who has to teach about 180 students in his class all they ought to know of practical and operative surgery and instil into their minds all the varying features of a tiresome nomenclature of surgical diseases, has undoubtedly a very huge task to perform. When it is remembered also that a gentleman holding the position of a representative surgeon to a large educational institution is not expected to scamp his work day by day, or to ride rough-shod over his responsibilities towards his profession in regard to advancing original scientific research in his particular domain, when we find that such a man is naturally expected to be not only a skilled

operative surgeon, but a lecturer and teacher in the department of surgery, we are clearly told that the fulfilment of such a task is almost, if not absolutely, impossible for him to do the work of a general practitioner besides. For just as truly as the British system declares that a man cannot serve two masters, so it is demonstratively true that a medical official fully performing his State-paid duties cannot find time to be a private practitioner. There is no evading this view of this question. A surgeon and a professor to one of our hospitals in London is very differently situated, both in status and work, to a doctor holding the same position in one of our Indian Hospital Colleges. In London, we find the surgeon to Guy's Hospital, for example, is a man who stands pre-eminent in surgery. He is assisted by a staff of surgeons and assistant surgeons, who in their turn are men head and shoulders above their comrades. Here in India the surgical or other professor is manufactured by Government edict, and has merely the assistance of a newly-fledged junior army surgeon and a babu assistant-surgeon, who are absolutely without any real experience worth the name. The responsibility therefore of prescribing and generally caring for the patient lies morally upon the surgical professor. We stated that such an officer had 70 patients to care for. Allowing that each patient on an average requires even so little time as 5 minutes for attention to his or her case, this would involve a stay of at least 5 hours at the hospital. But surely some cases would need more than 5 minutes of the surgeon's attention, and this would necessarily further prolong his stay in the hospital wards. Then we have also the fact that this officer has to teach about 180 embryo saw-bones the mystical art of enucleating tumours, amputating limbs, tying arteries, and leading them through all the meshes and intricacies that are involved in the study of clinical surgery. Who will dare to declare that these are not onerous and laborious duties? Where can such a thoroughly occupied mind find leisure for multiplying its cares and responsibilities by under-taking the duties of a private physician to numerous families in the city, or of being the medical advisor to several private schools, insurance offices, pension funds, and various trading houses.

Be it remembered always that such a man's time and talents belong primarily and legitimately to the surgical inmates of the Medical College Hospital to whose aid he is liable, at any time of the day or night, to be summoned. To consider only the solitary interests of the poor patients whom the Government pays him to attend, how can it be possible for the man, who is liable, at any and all times, to be called to attend such patients, to be able to obey the summons when it comes, if he is busily engaged in private practice during every spare moment he is outside the four walls of the Medical College Hospital? We maintain without fear of contradiction that every Government doctor who is engaged as a professor of any branch of medicine in any of our College Hospitals has more than enough to do of *State work*—if that be done efficiently and thoroughly to leave him no more leisure time than secretaries to Government, or judges or engineers or educationalists have when their day's work is over. We have heard it said that many a zealous professor of the Medical College has conscientiously declared that were *private practice*, by the professors, put a stop to, our Colleges would become more popular, our students be better educated, and medical science and original research advance by leaps and bounds. To add to this long list of official burdens we have the fact that these Government doctors are bound, as an act of duty, to attend free of charge, all servants of the State who require their services in times of sickness. This latter task would be gigantic enough in itself.

men are actually studied of by those who are entitled to the highest medical knowledge. Yet how many a Government servant doctor has seen with the painful ordeal of inviting to his aid the Government doctor who is careworn and dead-beat by his self-imposed struggle in the domain of private enterprise! The sufferer is invariably told to go to the Government hospital, where he will receive regular attendance, and he must follow this course at the maximum of discomfort to himself and the minimum of labor to the Government-paid doctor. When it is remembered that these Government doctors are supposed to hold the dignified position of professors and consultants in their various specialities, is it not inconsistent or rather *infra dig* that they should trot about as the rivals of the general family physicians? Were they to occupy their rightful positions as consultants and adhere strictly to their special lines of work, doing all in their power to make themselves eminent by their diligence and original research, we might be justified in claiming for the public and for the general body of practising physicians, that these men be allowed the privilege of being used as consultants pure and simple. We believe that as consultants there is every reasonable hope of a really lucrative addition to their official income by such special practices, and we maintain that when so specially qualified, the limitation of Government doctors to consulting practice alone is what the occasion and the necessities of the public and of the independent medical profession urgently and imperatively demand.

MEDICAL CERTIFICATES AND THE BENGAL GOVERNMENT.

ALL over the civilised world it is urged that State-competition, whether in merchandise or in professional services, is decidedly unjust to the subject; but here in India, where private practitioners are plentiful and medical certificates obtained a gold mohur (£1 or \$5) ahead, the Bengal Government (No. 298 T. M. of 11th September 1895) has just ruled that medical certificates required for the purpose of leave, retirement or fitness for State employment must in future be signed by Presidency Surgeons, only, of the Indian Medical Service, and that a fee of Rs. 4 (£0-4-5 or about \$1-08) is to be charged for such medical examination. Thus adding another heavy strain on the members of a service who are already complaining that they are overpowered and broken down by the magnitude of their duties.

Inconsistency is alleged to be a feminine failing, but it scarce savors of consistency or of sense that the same body of men, who, in England, accept as valid medical testimony, given by students just out of college, respecting the extension of sick leave of Indian Officials on British furlough, should officially announce that such certificates for State purposes in India are to be monopolised by Presidency Surgeons and forthwith publish a list describing those persons, who cannot obtain casual leave or furlough for ill health without producing a medical certificate signed by a Presidency Surgeon; but which list unfortunately embraces 40% of the official world, 44 of whom have hitherto had their own private family physicians who were lawfully empowered to place them on the sick list, excuse them from duty or recommend them furlough when absolutely necessary to do so.

Not very long ago, when we wrote the Government on this subject, we were informed that no rule obtained against the acceptance of private practitioners' medical certificates as evidence of fitness, and that there was no reason why they should require counter-signature by Presidency Surgeons, no matter whether the party producing such a certificate was a Government servant or not. This notification of the Bengal Government practically vitiated the significance of

Secretary made us, for it was up into the Presidency Surgeon's case-book every one of the officials of the Law Office, and disparages the medical diploma: it has itself granted to qualified students and deliberately robbing the private practitioner of his acknowledged rights defends him of the very advantages truly assured him when accepting his fees for tuition.

We do not pretend to guess the motives prompting or the official under-current that urged or compelled the Lieutenant-Governor to publish this "Hat of State monopoly" at the very time when friction and bitterness were very high indeed between the official and non-official; but we know and feel that this notification seriously affects the private medical practitioner; for it as good as plainly tells him "Starve! You feed starve or commit suicide, for all we care, so long as we secure our taxes and your tuition money, the Municipality their license fees, and our doctors the whole of the private practice"; for does it not follow that if the Presidency Surgeon is compelled to treat him gratuitously and mendicantly for a paltry fee of Rs. 4, *anous propre*, gratitude, or whatever one may like to call the feeling, will suggest the propriety, or return compliment from the official husband of engaging the *cas* physician for the whole family and dismissing the private practitioner who hitherto ministered to the illness of himself or his wife or his children?

Surely the Government might wisely retract this notification and thus remove the unjust and undeserving stigma it implies to private practitioners; for there are laws already extant to render it powerful enough to *severely* punish any delinquent, who exposes himself to the charge of dishonestly granting a medical certificate and a deterrent influence could easily be exerted against recurrence by gasetting any offender (official or non-official) and totally excluding him from future granting of such certificates.

ETHICS OF MEDICAL CERTIFICATES IN CROWN CASES.

So, after all the row, fuss and unnecessary insults hurled at the certificates of civil medical practitioners, the Sessions Court has quashed the conviction obtained at the Sessions Police Court against JOHN E. CROFT for the alleged illicit manufacture of brandy and whisky; because the *oral* evidence tendered by the Chemical Examiner to Government not only materially differed from the *written* testimony submitted by that officer on the same subject, but also contradicted the story of the prosecution.

It is seldom indeed that a case before the law courts has been characterised with the inconsistencies peculiar to this one and its curious phases:—(1) The defendant, CROFT, who was a chronic rheumatic, had a sudden return of his gout and consulted DR. J. B. WALLACE, who certified to that effect, but the Magistrate refused to accept the certificate on the plea that DR. WALLACE was not a Presidency Surgeon. (2) The Secretary to the Bengal Government wrote to the effect that the Magistrate was wrong in this instance. (3) A similar certificate signed by the Coroner, DR. E. W. CHAMBERS, met a like reception, and a warrant was issued for the arrest of the bed-ridden man, MR. CROFT. (4) The prosecution closed its case and rejected the Chemical Examiner's certificate, but as soon as the defence made a clean fight towards victory, the report of the Chemical Examiner was rushed in as evidence against the defendant, who was *denied* the privilege of cross-examination. (5) Objections were raised by the prosecution were immediately recorded, but those of the defence were over-ruled. No matter of how vital import. (6) Surgeon-Captain J. F. EVANS' report was accepted as evidence for the prosecution *without* cross-examination; but when he was summoned the Magistrate held that he was a witness for the defence, who could only examine DR. EVANS

in chief, while the prosecution could cross-examine him if it liked to do so. (Y) As the report of the Chemical Examiner was unique in respect of being qualitative instead of quantitative Dr. BOOTH & DREW was engaged to instruct Counsel for the defence, but the prosecution objected strongly to this proceeding, and after considerable argument their objection was over-ruled with the proviso that the Chemical Examiner was not to be questioned on the weak points of his report. (Z) Though the evidence against him was completely rebutted Mr. GUYOT was convicted and fined heavily; but the Sessions Court has quashed the conviction and remitted the fine.

KALA AZAR IN ASSAM.

COMPARING results obtained by actual research made by himself against the causation hypotheses started by the Sanitary Commissioner for Assam concerning this mysterious but highly fatal disease, Dr. J. DODDS-PRICE advances sound reasons against malaria or ancylostomiasis acting as the exciting cause; because (1) cases of *kala azar* run their entire course without a single worm being discovered in the motions during life or in the intestines after death, and (2) the disease not only completely resists all antimalarial treatment, but also is distinctly contagious, which (latter) malaria is not. It is possible, thinks he for biology and the microscope to at some future time afford a strong clue to the cause, cure and prophylaxis of *kala azar*, but, so far, morbid anatomy reveals next to nothing beyond serous infiltration in pleural, pericardial and abdominal cavities and an enlargement of the liver (varying in extent) with a toughening and increment of the fibrous tissues. Pathology also is indefinite, and in many instances the patient does not know he is as ill as he really is; for he can enjoy and digest his food and will tell you that he has neither pain nor fever, only a feeling of extreme lassitude and "want of go" which make the lightest work impossible, yet the thermometer will register 103°F. Then the disease progresses rapidly, digestion and appetite fail, *cancerum oris* or epistaxis may come in as complications with anemia and cedema, bowel complications supervene rapidly and dysentery or diarrhoea usually terminates the scene; while in those cases, who have accidentally been snatched from the jaws of death, the constitution suffers so severe a shock that they suffer from general debility for a long time after convalescence.

VENEREAL DISEASE IN THE NAVY.

WHENEVER the necessity has been urged for re-instating the Contagious Diseases Act, it has been met with angry roars of disapproval, on the main plea that it demoralised women whose virtue was public property and their modesty an abstract quality. When the C. D. Act was in force, the spread of syphilis was severely controlled, as the heavy penalties, inflicted on the diseased, who plied their trade before they were properly well, had a strong deterrent influence; but since the repeal of the Act syphilis has simply run riot, and, though no correct statistics are forthcoming from the Mercantile Marine, the report of the Director-General of the Medical Department of the English Navy tells a truly terrible tale for last year (1894) when five men died and 9,321 men were incapacitated from work by reason of syphilis and gonorrhoea thus occasioning a loss to the Navy of 282,171 working days. Of those laid up 8,106 had primary syphilis and 1,593 secondary syphilis and 4,823 suffered badly from gonorrhoea and its sequelae. Appalling as these figures seem, they are really weak under the mark as about 35 to 45 per cent. of the afflicted are either ashamed or afraid to report "sick" and treat themselves secretly.

DUFFERIN FUND SCHOLARSHIPS.

THE Honorary Secretary to the Committee of Dufferin's Fund is calling for candidates for admission to the Apothecary scholarships of Rs. 25 per annum. The conditions required

are that the girls must have passed either the intermediate or the higher examination for women, and are prepared to serve for five years after qualification, with an alternative penalty of refunding scholarships drawn, plus 25 per cent. The advantages offered are permanent employment, sound medical education and a salary on the same scale as that of Civil Apothecaries. Applications must be forwarded to Surgeon-Major W. B. Browning at Government House, Ootacamund, Mysore, before the 8th instant.

A FRENCH SCHEDULE OF FEES.

WHEN France does anything, she does it with a vengeance or not at all. To obviate quarrels with the doctors' tariff the department of Yonne has prescribed the following fees:—1 franc for drawing a tooth, opening an abscess, or giving a hypodermic injection; 2 francs for applying a speculum, reducing a hernia by taxis, or applying a caustic; 3 francs for tapping a hydrocele, reducing a phimosia or setting a broken clavicle; 5 francs for circumcision, setting a fracture of the lower jaw, arm, forearm, leg, fibula, femur, administering chloroform, or reducing a dislocation of the elbow, shoulder, ankle or knee; 10 francs for removing a placenta, turning a foetus, applying the forceps, or reducing a dislocation of the femur and 30 francs for tracheotomy or amputating a limb. Calculated into Indian currency these fees range from 11 annas to 20 rupees and are not likely to find favor among physicians, whose minimum charge is Rs. 10 (i.e., 24 francs) for a consultation and Rs. 150 (i.e., 219 francs) for an ordinary confinement.

THE PHYSICIAN AS A CITIZEN.

FOR many and varied reasons there has, till recent years, been a tendency, on the part of physicians, to avoid all other than medical matters, instead of being well to the front in promoting improvements to advance the general civic welfare, educationally, politically, socially and otherwise. This is to be regretted as no one can be better fitted than the physician to grapple with the proper method to study or remedy social ills; for his education and his work ought to reveal to him the hidden springs of human action by bringing him in contact with the daily life of all classes of the community and that very medical training, that urges him to look closely into the cause and effects of disease and suggest their amelioration or removal in the individual, teaches him the right way to go about the treatment of the community, which is merely a larger organism.

DEATH IS PAINLESS.

MAN, but to live a spell, extend his race and die was born, and in this respect Nature built him no better than the rest of animal creation, yet from the pulpit and from sombre lips are daily sounded the alarm of the terrible death struggles of those who have not lived religious lives; but DR. CYRUS EDISON brings forward overwhelming facts and logical conclusions proving that if these pictures are supposed to be taken at the moment of death, they are utterly false as (homicide, murders, suicides and sudden or violent death excepted) several hours before final dissolution, of 99½ of every 100 human beings, a merciful unconsciousness sets in, dwindling charity, love, sympathy, majesty of intellect and pride into nothingness, as without a pang or struggle that mysterious force, we call life, slowly ebbs away from its last citadel the heart making "what is" become "what was"—This then is death.

A FAST BOY.

In the year 1729, says *Good Health*, was recorded by the French Academy a case of a boy who at the age of six years attained 5 feet 6 inches in height; grew a full beard and was able to lift a bag of grain weighing 200 lbs. Two years later he became grey. At ten his teeth fell out, his hands were palsied and he tottered like a man of sixty-two years; later he died with all the signs of old age.

INDIAN MEDICAL PROVIDENT FUND.

The following have sent in their names as willing to join the above Fund:—Asst. Surgs. W. J. Montgomery, Basim, Bano, J. H. Bodricks, Alipur; J. R. Machado, Poona; H. Dalby and W. J. Marshall, Darjiling; J. E. Heppollette, Pachmar; W. Heathcock, Dagbhai; E. W. Fraser, Lucknow; H. V. Dewey, Jalala; S. Killoway, Mooltan; H. D. Pant Ganda; Tim Baptist, Ferozpor; J. G. Fleming, Suri; Mr J. Williamson, C.M.S., Visanagram; T. A. Ambrose Pillay, C.M.S., St. Thomas' Mount, Madras; E. Reuben, C.M.S., Mahud, Colaba; M. M. Arasthunkar, C.M.S., Merta, Marwar; C. Senkelchand, C.M.S., Jalul; C. Vedyantaya, C.M.S., Ambarasodiam, Tinnevely; H. D. Pantalu, C.M.S., Thanawadi; P. S. Jesudasan, Kulital; G. C. Das, C.M.S., Sipaghur; C. B. N. Rao, C.M.S., Hormali; S. S. Budin, C.M.S., Sukkur; S. K. Naidu Bhimavaram, Godavery District; Dr. George E. Claxton, L.R.C.P. & S., Nainital; Dr. H. C. Banerji, Tharawaddi District; Dr. Ed. L. Chalke, M.D., Chatrapur, Gunjam District; Asst. Surgn. W. Fullam, Peshawar; Jai Kishan Das, L.M.S., Kulu; Dr. P. C. Ghose, Arakan Hill Tracts; Dr. B. P. Chatterji, Khumbhir; Mr. Bhooraya Jullaya, C.M.S., Goona; Asst. Surgns. M. E. Mungavin, Darjiling; E. J. Greson, Cherat. This makes a total of 65 applicants. We need 35 more to complete the 100. See page 183 of our issue for full particulars, and let all interested send in their names without delay.

AN UNJUSTIFIABLE JOB.

OUR contemporary—*Pioneer*—is dissatisfied at Dr. DYSON being appointed Sanitary Commissioner of Bengal; characterising it as an "unjustifiable job;" and pointing out that Dr. DYSON is no doubt energetic, capable, and popular, but that Surgeon-Major LAWRENCE WADDELL has better claims. After giving an account of the latter's professional career and attainments, that paper remarks that Dr. DYSON has not a tithe of Dr. WADDELL's knowledge or experience, and has not yet shown any talent for original research. One or two such blunders will go a long way towards producing widespread dissatisfaction in the Medical Service.

MEDICAL HEROISM IN THE CHINO-JAPANESE WAR.

THE *Broad Arrow* speaks in glowing terms of the unflinching courage shown by the Japanese Red Cross men who were always "well to the front" with stretchers and first-aid appliances for their comrades and, in spite of the withering fire from the enemies' guns, did not hesitate a moment on their errand of mercy, but went about the battle field, picking up the dying and wounded, as calmly and stolidly as if they were on the parade ground or under review-inspection.

A FEMALE ARMY-SURGEON.

The *Progressive Medicalist* revives the story of a woman doctor, in disguise, in the British Army, some 40 years back. Scores of folk out here remember the brilliant Surgeon Macleod, who was kind, grave and well up to his work but very reserved. This reserve so annoyed a brother officer that he twitted the doctor with living like a woman and got a slap upon the face in response. A duel ensued in which Surgeon Macleod killed his opponent and almost immediately resigning his post left India for England where he died, after several years, and it was only then discovered that Surgeon Macleod was a woman and a direct descendant of one of the oldest families of Great Britain.

GRATIS ATTENDANCE ON DOCTORS' FAMILIES.

The following is the more essential part of the rule relating to the gratuitous professional services to the faculty, which has a direct bearing on the case referred to: "All legitimate practitioners of medicine, their wives and children, while under the paternal care, are entitled (not as a matter

of right, but) by professional courtesy to the gratuitous and gratuitous services—railway and like expenses—except—of the faculty, resident in their immediate or near neighbourhood, whose assistance may be desired."—Code, Chap. II, Sect. 2, Rule 1.

SHORT ITEMS.

The winter session of the Madras Medical College opens to-day but DR. MAITLAND, the Principal, has issued a *casco* that, except he be disfigured with pits and produce a certificate declaring that he had had smallpox after he was ten years old, no new student will be allowed to enter the curriculum till he can produce satisfactory certificates of vaccination and re-vaccination.

Referring to our remarks on the suggestion of some service man in London to appoint an I.M.S. officer on the India Office Board as its Sanitary Adviser the *Englishman* says:—"At the risk of being accused of impertinent curiosity we venture to ask to what degree India could expect to benefit from such an addition to the already overgrown body of officials in London."

Authentic copies of Mr. Ernest Hart's address on Indian sanitation have been supplied by *special request* to the India Office in London. Though it might seem a wild expectation, still it is to be earnestly hoped that official notice will be taken of the somewhat trenchant criticisms on India's sanitary needs and the placing of the public medical services on a rational basis.

The William F. Jenks Memorial Prize of \$500 has been awarded to Dr. A. Brothers, of New York, for the best essay on "Infant Mortality during Labor, and its Prevention." The writers of the unsuccessful essays can have them returned to any address they may name by sending to Dr. Horace V. Evans, College of Physicians, Philadelphia, U. S. A.

A native paper in Calcutta writes:—"Nothing unites the youth of the country for physical labor so much as the education they receive in our universities. The banking after service is the bane of national progress, and nothing will check the poverty of the country unless the minds of the people are directed to nobler schemes of life."

As the result of the new system of sewerage in Rangoon, Dr. Sutherland, the Medical Officer of Health, reports that in the opening year 1890, the death-rate in the Tarokten and Sule divisions exceeded that of the whole area of the town, whilst in 1894 fell to less than for the whole area. Comments are superfluous.

The new Medical College building in Calcutta promises to be ready in time for the cold season's dissecting classes. The dissecting room will be a very large hall, with a well lighted and ventilated gallery. The rooms will be lined with glazed tiles (white), and have a white marble flooring.

It is significant to notice that the disappearance of the dysentery epidemic in the Sussex Regiment at Dum-Dum has been simultaneous with the abolition of the filters, previously in use by the men, and the introduction of a system of boiling the whole of the drinking water.

The Secretary of State has been asked to send out five lady nurses in the places of those retiring and to fill one vacancy. Fourteen lady nurses are desirous of extending their services for another five years, but stipulate for furlough, first, for various periods which the Government of India decides to allow.

Surgeon Captain P. Rebb, R.A.M.C., has taken 3 months' leave and left Bombay on 21st ultimo.

The annual returns for all India showing the mortality from wild beasts and snakes show, practically the same figures as in 1922, being 2,692 in 1924 as against 2,604 in the previous year from wild beasts, and 21,235 against 21,515 for snakes.

The sales portion of £100 per annum allotted to the Madras Medical Establishment for the year 1895-96, has been conferred on Dr. A. L. Hackett, lately retired, with effect from the 4th May 1925.

Though cholera has abated at Bangalore, the Government of India have appointed Surgeon-Major D. Rose to investigate and report upon the cause of the outbreak.

The Health Officer of Calcutta states that the health of the town is fast approaching the state when Calcutta possessed no drainage.

Mr. W. J. Lubeck of Madras has passed the L.S.A. London.

Current Medical Literature.

MEDICINE.

The Influence of Alcohol on Sexual Perversions, Epilepsy, and other Psychological Anomalies.

DR. FOREL calls attention to the fact that the inordinate use of alcoholic beverages not only leads to the development of the ordinary alcoholic psychoses, especially delirium tremens, but it also plays a prominent role in psycho-pathology in two different ways: Firstly, the hereditary pathological predisposition of certain persons is such that they cannot indulge in alcohol moderately, but become dipsomaniacs at once, if they do not abstain all their lives. Secondly, alcoholic intoxication either stimulates or develops directly any latent psycho-pathological germs that might otherwise have remained latent. In the current casuistic of sexual perversions the principal factors enumerated are congenital and acquired dispositions, acquired nervous or mental disorders, and, in some cases, bad habits. There is no mention of alcohol as a causative factor. FOREL observed cases in which the use—or abuse—of alcohol was a most prominent feature, and enumerates diverse illustrative histories. It is an established fact that epileptics stand alcohol very badly, and when intoxicated are especially dangerous. There is also an alcoholic epilepsy, the subjects having fits only when intoxicated. FOREL also alludes to the "pathological" intoxications, followed by amnesia, and concludes that nearly every psychosis is aggravated by the use of alcohol. Other psychoses which are either caused or kept up by alcohol are, for instance, alcoholic mania, melancholia, pseudo-paralysis, incurable secondary dementia, acute and chronic hallucinatory folly, etc. FOREL observed many cases cured by abstinence, and considers indulgence one of the greatest obstacles in the radical cure of morphino-mania. He had always observed that the excitement of the insane in asylums was always greater after entertainments at which wine or beer were served. At Burghell, of which FOREL is Director, alcoholic beverages have been substituted by milk and lemonade. He commends following the example of the London asylums and that of Knapelin, in Heidelberg, by prohibiting the use of alcoholics.—*Jour. of Nerv. and Ment. Dis.*

Displacement of the Liver.

J. E. GRAHAM, of Toronto, has a paper on this subject in the *Canadian Practitioner* for June. He states that displacement of the liver may occur from influences outside the liver and its attachments, such as tumors, abscesses, and

the like, as well as from displacing or compressing causes, such as length of the ligaments, ribs, and spine. The displacement is not uncommon in women with obstetrical conditions. They have borne many children. A distinction is to be made between floating liver and merely movable liver. The latter reports the case of a woman, aged 22, who had twelfth children, and presented cyanosis, dyspnea, dilatation of the right heart, and emphysema. The liver was displaced downwards, but could be replaced when the patient assumed the recumbent posture, and could be retained in place by the use of a bandage. In a second case, that of a man aged 27, the liver was displaced by a subphrenic abscess. There existed also pyloric obstruction and gastritis. The liver lay obliquely in front of the stomach. In a third case, in a boy, the front wheel of a waggon had passed over the trunk, fracturing the seventh and eighth ribs. For a time a considerable area of dulness was found upon the left side, while the normal area of hepatic dulness could not be detected, so that the question arose whether the liver was originally displaced and an inflammatory process had taken place in the right hypochondrium, or if the liver was merely hidden under the diaphragm, and an inflammatory process had taken place about the spleen. The paper contained a tabulated statement of 30 published cases of displacement of the liver.—*B. M. J.*

The Etiology of Pneumonia.

AN esteemed correspondent, who has, he tells us been in practice for upwards of fifty years, thinks that the key to pneumonia, bronchitis, and other internal inflammations is not to be found in the infection by specific germs, but rather in autogenous poisoning. He points out, for example, that pneumonia is often secondary to the specific fevers, and that bronchitis may be one of the earliest manifestations of such a fever. But apparently he thinks a greater share in the production of these inflammatory disorders is taken by depraved blood states due to defective digestion or metabolism, and affirms that the onset of pneumonia is paralleled by the equally sudden and familiar attack of arthritis characteristic of acute gout. In other words, he adopts a humoralist pathology in contradistinction to prevalent bacteriological doctrine. In this respect he would find himself in line with advocates of uric acid retention as the efficient cause of a vast number of internal diseases. Nor would we deny that there is much to be said in favor of such ideas, which go far towards explaining the occurrence of secondary pneumonia, pericarditis and the like. On the other hand, the adoption of the belief in the necessity of external infection would relegate all these blood states to the region of secondary rather than essential causes. It is not difficult to conceive that, given certain states of nutrition or rather demnutrition, the tissues are rendered more prone to attack by specific agencies such as the pneumococcus.—*Lancet.*

Neurosthenia and its Treatment.

SALLARD makes five clinical classes of this affection according as it is specially connected with the alimentary, cardiac, cerebral, genital or optical system. The diagnosis is more or less difficult owing to the inconstancy and variability of the symptoms, chief among which are: sensation of weight in head, mental depression, muscular weakness, constriction at nape of neck, pain in the back with tender joints, and dyspepsia. By way of treatment he suggests rest, careful hygiene and hydrotherapy. Vigorous use is made of electro-therapeutics and baths on proper application of the agent, which undergoes considerable change, the acidity increasing and a large amount of the fatty acid, lactic acid, and other incomplete oxidized products; but the urea, ure-

and the sympathetic system are decreased. G. H. KANAK, M.D., London, reports that as the result of localized toxic infections in the vasomotor system tenderness of the limbs, and agreeing strongly in favor of thermotherapy, is the production of hyperemia of the skin by artificial means such as heat causes a sudden efflux of blood to the skin with increased circulation in both the tissues and nerve endings. Consequently the exposure of the naked body, for a few minutes, to a temperature of about 85°F produces a vigorous reaction and exhilaration.

Early Diagnosis of Diabetes.

As treatment in the early stages of diabetes offers considerable hopes, if not actual certainty, of recovery Von Noorden, who depends greatly on the diagnostic value of alimentary glycosuria, views gouty and adipose subjects as more predisposed than any one else to diabetes, and declares that there is no wisdom in delaying treatment until the diagnosis is made by the accidental discovery of sugar in the urine, when perhaps the disease may have too far advanced. He points out that there is nothing more simple than the grape-sugar test which should be tried in the adipose and gouty (especially when there is a family history of diabetes) It is his firm conviction that adiposity is frequently an early symptom of diabetes, for though no sugar can be found in the urine of adipose individuals when fed upon food, consisting largely of carbohydrates, still, as soon as pure grape-sugar was eaten by those predisposed to, or having the slightest trace of, diabetes, glycosuria was manifested.

The Diagnosis of Intestinal Rupture.

DR. BERNY discusses the question of intestinal rupture from the diagnostic point of view, emphasizing not only the difficulty of establishing the certainty of a lesion of the gut-wall, but also the importance of so doing in order to enable the surgeon to undertake an early laparotomy. The effects of a severe contusion are very similar to those produced by rupture, but the author points out that while vomiting is present in both cases, its nature varies so much as to constitute it an important element in diagnosis. In simple cases of shock the vomiting is reflex in character, and, although repeated two or three times, is never very serious. On the other hand, where the intestine is ruptured, it is due to the extravasation of the gaseous and fluid contents of the bowel into the peritoneal cavity, and is then always of a persistent and intractable character. Berny recent investigations are added in which this opinion has been strikingly confirmed. —*New York Med. Journ.*

SURGERY.

Massage in Fractures.

Bump leads for the more extended use of massage and early motion in the treatment of fractures, in order to prevent the atrophy of muscles and the stiffness of joints so often observed under the old-established methods of complete immobilization. In fractures of the shafts of long bones immobilization of from ten to twenty days, according to the size of the bone, is necessary in order to ensure the presence of sufficient callus, and then massage, followed by active and passive motion of the limb, should be commenced as soon as motion is at all firm. In fractures, involving joints, Bump recommends preliminary massage, then immobilization for four to eight days, finishing with daily massage and passive movements. In fractures of the pelvis and cranium he begins massage and passive movements. The method is recommended by great

celebrity, unusual mobility, or septic infection. In 1895 we agree with Bump's method; so doubt, as every case managed and passive motion is too much neglected or not commenced early enough, especially in fractures in which joints are involved. In fractures of olecranon or patella we think he would be a very bold (and somewhat risky) man who started "straight away" with movements. —*Med. Times and Hosp. Gaz.*

Iodoform Injections in Joint Disease.

FERRAS reports the case of a man, aged 37, who after a long walk first noticed pain in the right knee, which was uniformly enlarged, red, and tender, and contained fluid. The joint was insensate, and a considerable quantity of fluid was let out. Two or three weeks after this, during which time the joint went on well, a small abscess formed in the upper third of the tibia; this was scraped. A similar purulent focus also appeared in the shaft of the tibia. The knee-joint became worse. The author then tried intra-articular injections of iodoform emulsion in sterilized glycerine (1-10) at intervals of twenty to twenty-five days. After each injection there was fever of maximum grade on the second or third day. The tubercle bacilli were found in the joint secretion. Slight improvement followed the injections, which were used five times, but the patient not being satisfied, resection of joint was finally done. It was then seen that the cavity was full of a mass of adipomucous-fibrous connective tissue, the caseous substance being almost all gone, the osseous foci cured or in process of cure, and the tuberculous nodules undergoing fibrous change. No bacilli were now to be found. Probably the iodoform acts by exciting a reactive inflammatory process with formation of new connective tissue.

Death by Lightning.

DURCK describes the morbid anatomy in the case of a man struck dead by lightning. There was an abrasion of the skin on the left side of the forehead where the current entered. There were extensive hemorrhages over the left parietal, frontal, and temporal lobes. Fluid blood was found in the heart and veins. There was hyperemia of all the abdominal organs and chronic enlargement of the spleen probably malarial in origin. The brain substance was very soft, but without edema. The author thus summarizes the results that have been found in recorded cases of death by lightning or by the electric current. (1) The blood is dark, in coagulating power, which latter may even be entirely lost. (2) Circumscribed extensive hemorrhages due to the tearing of vessels in the course of the current are generally present. (3) There is frequently a destruction of parts of organs. (4) The site of the entrance and exit of the current is usually marked by superficial or even deep wounds, resembling burns. As regards the figures on the surface of the body further investigation is needed to establish their direct relation to the electric current. —*B. M. J.*

Suprapubic Cystostomy for incurable Vesico-vaginal Fistula.

DR. EMER reports a case of incurable aggravated vesico-vaginal fistula in which the destruction of the parts being so great that it was impossible to construct a new sphincter in the usual manner, he performed suprapubic cystostomy, using the edges of the divided skin and of the opening into the bladder to form (by extending them together) a four-angled artificial suprapubic urethra, through which the urine passed, and its full retentive power was not gained, the opening was covered with a trans arrangement carrying a weak tube, which the overflow of the urine passed and the patient was kept dry.

Serious Effects of Serpent Venom absorbed through a Wound of the Mouth.

Dr. HIRSCHMORN has published the case of a man who suffered from the effects of serpent venom after sucking the wound of a girl who had been bitten by a viper. The girl recovered within a week, but the man had a painful swelling of the left submaxillary region extending to the neck, the chest, and the upper extremity, and he suffered also from vertigo, inability to stand, and clonic and tonic spasms of the left side of the body. The seizures lasted from half an hour to three hours, and after they ceased the skin assumed a reddish color with blotches elevated above the general level. This exanthema resembled urticaria and caused a sensation of itching, disappearing after two hours. The spasms and the aura ushering in the paroxysms suggested epilepsy, but there was no unconsciousness. Examination showed that the inoculation had taken place through the gum, which was lacerated in consequence of the extraction of a tooth. Dr. HIRSCHMORN supposed these paroxysms to be toxicemic; bromide of potassium was administered, and the patient is at present free from them.

Double Castration.

The results of 111 such operations performed for senile enlargement of the prostate are summarised by Dr. J. WILLIAM WHITE who declares that theoretical objections fade under clinical experience, and quotes the following percentages:—mortality 18, uremia 7.1, recovery, with rapid atrophy of enlargement 87.2, disappearance or lessening greatly of long-standing cystitis 52, return of the vesical contractility 66, return to normal of local abnormalities 46.4.

Spleen extirpated for Echinococcus cyst.

A woman aged 85 had a tumour as large as a child's head in the left hypochondrium, but freely movable and little sensible. HAHN cut down on it to find a thin bluish-black capsule, but speckled with yellowish-white spots and closely impinging the spleen, with which it was bodily excised and the splenic pedicle doubly ligated. There were no complications, and patient made a speedy and complete recovery.

Palliative treatment of jaundice due to malignant obstruction.

The most perfect cases for operation are those in which the lesion is confined to the head of the pancreas, and a distended gall bladder would warrant operation by tapping if the obstruction were below the cystic duct; but if the obstruction were above this point, the gastric symptoms would be best relieved by medicinal treatment and removal of the jaundice. RUSSELL, however, relates a case where a woman, of 85, had intense jaundice and profound cholemia, but as her symptoms partially contra-indicated it, she declined surgical aid, till it was too late, and died in 30 hours after she was tapped. The post-mortem disclosed primary carcinoma of the head of the pancreas, without secondary involvement.

OBSTETRICS AND GYNECOLOGY.

What to do and what not to do is the question.

No branch of a physician's practice requires more self-poise, and where so many complications arise, commanding our sympathy and demanding our skill, as that of obstetrics, and when disease and death follow a normal case of labour the cause can be traced to none other than to ignorance or mismanagement.

With these preliminary remarks, I now advance a few

Algorithms relating to Obstetrics.

1. Examine the urine a week or so before the expected time of delivery. Albumen need not occur, albuminuria present in large quantity, in which case the woman should be restricted to milk diet, 1-10 grains of sulphate of potash four times a day, and the bowels kept open with cream of tartar, the object being of course to relieve congestion of the renal veins.
2. Make no digital examination without first cleansing the hands and nails, together with the external genitalia, with a solution of bichloride of mercury (1 to 2,000) and ethereal soap.
3. Empty the rectum thoroughly with an injection of warm water.
4. Make as few examinations as possible during progress of labor and each time dip the hand first in antiseptic solution.
5. If presenting part emerges slowly from the womb, do not allow your impatience to so get the better of your judgment as to induce you to "assist nature" by pulling upon the os. Probably all the deep pathological tears, calling for surgical interference, found on the right and upper anterior sides of the cervix, are caused by the finger of the accoucheur.
6. If pains are sluggish, change the position of the patient.
7. Do not rupture the "bag of waters" too soon, as it, when intact, favors the posterior rotation of the face.
8. Should a posterior rotation of the occiput occur, and nature fail after a reasonable length of time to effect a delivery, apply the forceps and turn the occiput to the front by rotating either to the right or left, as the position of the babe would indicate. This manoeuvre of the forceps can be executed without danger if care be exercised, turning the head not more than a quarter of a circle at a time, then pausing a moment for the shoulders to follow. After this is accomplished the instruments should be removed and reapplied.
9. In making traction on the child's head with the forceps, unlock them about every thirty seconds, else the engorgement produced by continued pressure of the instruments might cause a hæmatoma of the brain or dura.
10. To prevent a rupture of the perineum.

When the occupant is emerging from the vulva, remove the right hand from the forceps and with it support the soft parts, while with the left you continue slight traction upward until the bridge of the nose reaches the anterior border of the perineum, when the instruments are quickly removed. Now, in order to avoid a rupture, especially if an expulsive effort is being made, hold the head in statu quo until a relaxation takes place; then with the thumb and first two fingers of the right hand, push the perineum down and under the chin, allowing it to rest on the palmar surface of the fingers. The next pain will expel the head, which is grasped by both hands and pulled upward, delivering the under shoulder first.

11. Should a rupture occur, repair the injury at once, using the large iron-dyed silk.

12. Do not become impatient if the placenta does not follow quickly, but wait, say a half or even an hour, before an attempted forcible delivery is made. Should, however, a violent hæmorrhage occur, empty the uterus at once, by disinfecting the hand, introducing it into the womb, detaching the placenta, and allowing it and the hand to be forced out together.

13. The source of uterine hæmorrhage following labor arises almost always from the open and now no longer useful utero-placental vessels. Nature, usually, closes them out of a hundred, prevents hæmorrhage arising from this source by filling up these vessels with clots and placing over their mouths with coagulated blood. Therefore

14. *Massage, the Swedish method*, and for two reasons: First, that the act of squeezing out the placenta discharges at the same time from the arterioles and vessels this plastic substance, forming a mass of blood to follow the non-squeeze of the hand, causing in a probability a hemorrhage instead of preventing it. The second reason is, that a hemorrhage following after this method of forcible expulsion, necessitating, as it usually does, a constant hand pressure over the uterus for half an hour or more, while it may not prevent absolutely the reformation of nature's cement, would cause paralysis of the contractile fibres of the womb, rendering them incapable of responding to the stimulus of ergot or to anything else.

15. For these passive hemorrhages, where so soon as the hand is removed the hemorrhage goes on, the writer relies on 1 teaspoonful of laudanum rather than 2 or 3 of ergot.

16. After the birth of the child, gently knead the abdomen with the finger tips of the left hand, using barely force enough to feel the uterus beneath. This gentle friction excites uterine contraction far better than rough massage, expelling the placenta almost as quickly and is rarely, if ever, followed by unpleasant hemorrhages or after-pains. This slight finger pressure should be continued a short time after the placenta is expelled.

17. In early abortions, before atrophy of the blood-vessels of the mucosa takes place, the hemorrhage comes greatly from the engorged mucous membrane instead of entirely from the placental surface, as in full term. To stop it, do not use ergot or compression, but approximate the inner surfaces by removing the decidua with the placental forceps or the dull curette. This is to be followed by a hot antiseptic (preferably carbolic acid) intra-uterine douche.

18. Have the vulva kept well covered with sublimated cotton to catch the lochia and prevent infection; and, in addition, if a clean and competent nurse is in attendance, order given night and morning for five days, warm antiseptic vaginal douches.

19. Wash the babe's eyes the moment it is born, and in dressing the navel use boric cotton saturated with glycerin.

20. Restrict the diet the first three days only, after which have the bowels moved either by enema or the compound licorice powder. (If there is much flatus, use instead a full dose of castor oil and turpentine).

21. Keep the woman in bed two weeks, if possible, and the first four days give a capsule containing $\frac{1}{2}$ grain of ergotin and $\frac{1}{4}$ grains of quinine, morning, noon and night. This tends to prevent fever and hastens the process of involution.

22. If surgery is your speciality, and you are called to a case of confinement, use extra precautions in cleansing the hands and nails; in fact, it would be wise, if your practice in surgery is extensive, to let obstetrics alone.—*Gailard's Med. Journal*.

Obstetrical Brevities.

Sudden death due to employment of Sugar of Lead to procure Abortion.—MRS. B. had self-induced abortion fifteen times, successfully, but she tried it once too often and died in the act, without accomplishing her object. DR. PAUL J. HAMPDEN, who made the necropsy, found a 8-weeks embryo, in bed of uterus, with the membranes unruptured and endometrium yellowish white. In the vagina he found a pretty strong solution of lead acetate. As the organs appeared quite healthy and there was no history of heart-disease or disease of any kind, nor was there any sign of any injury to either the generative system or peritoneum, he concludes that death must have been instantaneous, and was due to the shock caused by the violent

MEANS believed in the popular theory that spontaneous rupture of the non-gravid uterus was a mythical apocryphal till he saw two cases, one where rupture occurred because there was haematomata with extreme retroflexion and in the other pyometra made the uterine walls give way. Both patients were successfully relieved by abdominal section.

Lactation Statistics.—Of 326 women, lying-in at the Freiberg Maternity, WISNOW found that during the first fortnight only 33 suckled freely, 44 secreted insufficient milk, and 299 had none at all; while 244 got through nature's requirements. The nipples were imperfect in 49 and swollen in 46 cases. He notes that the development of the nipple bears a direct relation to the milk-secreting power of the breasts, which latter he places in three groups of which he states the percentages to be:—bad 11, medium 21, good 54.

Treatment of foreign Bodies in the Uterus.—As with the exception of POULLEY all authorities are silent on this subject. ALBERTIN explains that foreign bodies may come from within—fetal debris, fibroma, calcified mole, polypus,—or from without—needles, plugs, sponges, catheters, hairpins, pessaries, knitting-pins, candles &c.—as the result of introducing instruments, &c., for the legal or illegal purposes of promoting premature birth and abortion, for therapeutic and surgical purposes of dilatation, cauterisation, replacements, &c. and for masturbation. He advises immediate aseptic removal of the foreign body, rest in the recumbent position for some days, intra-uterine irrigation and absolute cleanliness. If necessary the uterus should be curetted.

—10—

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Muscular Energy: Present State of Knowledge in regard to its source.

MANY and varied indeed have been the theories concerning the action of food towards muscular energy, and till very lately LIEBIG taught that as protoids were essential for the growth of living muscle substance, which had the power of liberating their energy, proteins were superior to the fats and carbohydrates, and the greater the amount of proteid matter eaten the greater the growth of the active muscles and the stronger the energy liberating mechanism; but after reviewing the whole of the evidence possible to be obtained, DR. D. NOEL PATON dishes the majority of the theories and, showing that it is *living* (protoplasm) and *not* dead protoids that we have to consider, points out that no matter whether the food be carbohydrates, proteins or fats this *living* protoplasm takes up the dead protoids from it, makes them parts of itself and converts their stored energy *alive* into the kinetic energy of muscular work, while the nitrogen in any excess of proteid, in the food, is rapidly excreted. Still he declares that a great deal of further research is needed before we can positively assert the why, wherefore, and how proteid metabolism actually affects the muscular work of the body.

Immunisation against Cholera.

SQUERNHEIM taking advantage of an epidemic of cholera at Buzeln, near Marburg in the Autumn of 1894, investigated the blood serum of patients convalescent from the disease with regard to its immunising properties. The blood taken from the median vein was kept for twenty-four hours in an ice-chamber, and the serum injected intra-peritoneally into guinea-pigs. Twenty-four hours later the animals were injected also intra-peritoneally with a fatal dose of cholera vibrios. These were of different origin, but in past years were obtained from the Buzeln epidemic. It was found that in the blood of such convalescent patients certain substances are present

which have a specific immunising property against the laboratory cholera of guinea-pigs. The amount and efficacy of these substances are not constant, but show variations bearing some ratio to the severity of the disease.—*B. M. J.*

Microbic Origin of Rickets.

MIRCOLI pleads for the microbic origin of rickets, believing that the disease is caused by the effect of ordinary pyogenic organisms upon the osseous and nervous system. Clinically he finds support for this theory in the fact that rickets develops independently of social condition; frequently begins with eczema, boils, or intestinal catarrh; occasionally; occurs epidemically; and is accompanied by fever, polyarthritic and bone pains, hydrocephalus, marasmus, and paresis of lower extremities. Pyogenic organisms have been found in the bones and central nervous system of rickety children. Experimental injection of pyogens into the bones and epiphyseal cartilages of young rabbits produced common osteomyelitis, but in other cases an osteomyelitis without trace of suppuration, with hypertrophy of the ends of the bones, hypertrophy of cartilages analogous to that of rickets, and marasmus.

Effusion and Absorption.

HAMBURGER points out the part that limitation of absorption plays in the production of passive effusions. The process of absorption is not a vital but a purely physical process; all tissues, living and dead alike, can take up a certain amount of fluid by imbibition either molecular, where the fluid is taken up by a homogeneous mass—for example, gelatine—or capillary, where the fluid is taken up by the pores of a porous mass for example, porcelain, or connective tissue. Given fluid in a pleural cavity, the cement substance between the cells or even the cells themselves, take it up by molecular imbibition; then, by capillary imbibition it is drawn into connective tissue, and thus reaches the lymph stream. This process, however, ceases unless the fluid thus drawn up be quickly taken into the blood stream, and carried away, for a limited quantity of tissue can take up only a limited quantity of fluid at a time. It is well known that quickening of the blood stream favors absorption, and it is the slowing of the blood stream, which by its purely physical effect in limiting absorption is an important factor in the causation of passive effusion.—*Virchow's Archiv.*

Vasomotor Phenomena in Fever.

REVIEWING the work done by many authorities and the theories advanced by others, Professor F. KRAUS concludes (1) elevation of temperature is coincident with diminished heat radiation, which latter is increased to a greater degree by antipyretics than by cold water; (2) during the stage of chill the central temperature is increased, but the peripheral temperature is lowered, the superficial arteries contracted and the skin turgescence diminished, while the venous blood is redder than in the normal state, (3) the vessels alternately contract and dilate; but cutaneous vasomotor reflexes are preserved, (4) the blood plasma and the number of red cells are not modified during fever; (5) toxic agents act upon the vasomotor nervous system and in some peculiar manner influence the thermogenic process and heat radiation.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Milk Borne Diseases.

TRACING an epidemic of cholera to its source, W. J. R. SIMPSON found the exciting cause was milk. J. M. COATES drank milk, got cholera, and died. KESSE, HANSEN, CHEW, ADAMS, FORSTH and a host of others have proved a distinct connection of raw milk with anthrax, tuberculosis, ty-

phoid and enteric fever, diarrhoea and dysentery. Dr. H. H. HERRMANN now reports an outbreak of milk-borne subacute enteric fever giving rise to the development of severe enteric in 80 persons, belonging to 12 families in Lancaster. KENWOOD records an unique case where a drink of raw milk gave rise to a peculiar sorethroat, terminating in true diphtheria and becoming the starting point of an epidemic of the latter disease at Finchley; but of so light a type that only one death was registered, and when the milk was boiled before imbibition the disease was stayed. Whether the actual source of the diphtheria KENWOOD would not like to swear, but he opines that the milk caused throat trouble, lowered the resistance of the tissues and laid the foundation for the subsequent diphtheria, and he therefore suggests the desirability of frequent veterinary examination of animals in dairies and cowsheds by some fully competent body.

The Sanitation of a House.

IN the suit of Paulson v. Judge, in the Queen's Bench Division on Saturday, May 18th, the plaintiff's case was that upon the representation of an agent that a furnished house at Sandgate, called Castle Glen, was in a perfectly sanitary condition, he hired it for the benefit of his family in the spring of last year; that immediately after entering into possession some members of his family had scarlatina, his wife had sorethroat, and his servants were also made ill from foul smells coming from the scullery sink and the dampness of the dining room. Evidence in support of the plaintiff's case was given by Dr. PAULSON, Dr. O'HEALE, and others. For the defence it was contended that the house was in a good sanitary condition, and the evidence of Mr. MARK JUDGE (sanitary engineer), was to the effect that the sanitary arrangements were perfect, and that he and his family had resided in the house both immediately before and after Dr. PAULSON, and had not experienced any ill-effects. The jury returned a verdict for the defendant on the claim and also on the counter-claim.—*B. M. J.*

Fees at the Coroner's Courts.

ALTHOUGH she had lain seriously ill from Monday to Saturday, it was only a few hours before her death and when too late for effectual treatment that her husband sent for Dr. W. J. MARCH to attend her. She died early on Sunday morning, and when the doctor was asked for a death certificate, he declined to give one on the plea that he had not seen sufficient of the case to be satisfied as to actual cause of death. A coroner's inquest followed at Bradford and not only did the jury formally register its dissatisfaction of Dr. MARCH, but the coroner, also, made some very nasty remarks about his refusal to grant a medical certificate, as well as spoke lightly of him to the jury and declared that if they wished to cite Dr. MARCH as a witness they could do so, but he would not permit a fee for such attendance at court. Our contemporary, the *Lancet*, rightly waxes wrath at this and argues that if the doctor were subpoenaed to attend court, it is nothing but fair that he should be recompensed for the loss of time and money occasioned by such attendance and a miserable guinea (£1-1-0 or about Rs. 16) is none too much. The medical man is the best judge as to whether, he should or should not grant a certificate of death. It is wrong to coerce him to certify against his conscience or in doubtful deaths, and whatever scientific facts or flaws he may wish to make public concerning an inquest should be made public on oath; but this is no reason why he should do so for nothing. It may be his moral duty to assist a coroner as much as he can if that gentleman is a layman; but the moment that that coroner forgets what becomes a gentleman the doctor's obligation to help him ceases.

Definition of an Habitual Drunkard.

A **RETIRÉE** has been presented to the English House of Lords, saying that any person who has been twice convicted of drunkenness, within two years, shall be defined to be an habitual drunkard, and that any licensed dealer serving or harboring him, after due notice, shall be liable to penalties and forfeiture of license. In South Australia three convictions, within six months, constitute an inebriate an habitual drunkard. An Inebriates' Bill, which was before the late Parliament, but failed to be acted upon before the dissolution, proposed three convictions within twelve months.

The Feeding of Patients.

It is just as well not to ask the patient what he would like to eat. Prepare what seems in the judgment of the nurse to be acceptable and bring it in at the proper time. Give little at one time, remembering that food taken little and often is the best rule during convalescence. Be very careful not to crowd too much on one plate. Simplicity is appreciated by a patient.—*Popular Health Magazine*.

Care of the Teeth.

It should be mentioned, in the interests of antiseptic purity and suffering humanity, that a good stout tooth-brush, plenty of water, and some antiseptic dentifrice, applied morning and night, afford a greater safeguard against many diseases than many people are aware.—*SIMS WOODHEAD*.

THERAPEUTICS AND PHARMACOLOGY.**Therapeutic Brevities.**

To disguise the taste and color of *cod liver oil*, mix 620 grains of the oil with 30 grains of freshly roasted coffee and 1½ of animal charcoal. Put into a stoppered flask, which put for 15 minutes into a water-bath at 140°F, shake occasionally for 2 or 3 days and pass through filter paper. The oil is colorless, limpid, and smells, and tastes strongly of coffee.—*Times and Register*.

ICHTHYOL was used successfully, in 2 to 3 per cent solution, by **SONENBERG** in the treatment of acute *pharyngitis*.

CALCIUM CHLORIDE, in 10 to 15 grain doses every 2 hours, controls *hemoptysis*—**S. SOLIS COHEN**.

NEURASTHENIA may be greatly benefited by giving ½ grain cocaine hydrochlorate and 1½ grains vanilla sugar, 2 or 3 times daily, in a glass of milk.—**GRLEY**.

BROMINE, topically used in 6 per cent. solution, acts as a specific in the early stages of *diphtheria*—**ROBERTSON**.

HOT WATER (as hot as can be borne) poured from a little height on to the back of the head will relieve *occipital neuralgia*.—**W. D. MOAFFEN**.

CELORAL may be disguised in ordinary gaseous (or aerated) lemonade, is the verdict of **DR. HOLLAND**.

CHLORINATED LIME, in the form of liquor caloris chloratæ is highly recommended, in *pruritus ani*, by **ALBERT R. REBERG**, who claims brilliant results, and declares that the itching vanishes, as if by magic, if the parts are washed in the above solution and left undried.

TINCTURE OF CANTHARIDES, given every 8 hours, will remove *incontinence* depending on debility of vesical sphincter, provided that the bladder, kidneys and stomach are free from inflammation.—**HARRIS**.

CALCIUM SULPHIDE, in daily doses of 1 grain, acts as a prophylactic in *influxus*.—**GREENE**.

GLYCOLYTIC FERMENT, prepared from the diastase of malt, is not diuretic, yet it gives marvellous results in the treatment of *diabetes mellitus*; but unfortunately the improvement is only temporary.—**LIPKIN in Rev. Med.**

PHENACETIN, when combined with citrate of caffeine, is far more effective than when used alone for *headache*.—**DR. CATTANACH**.

VALERIANATE of caffeine acts like a charm in *asthma* and hay asthma.—**HUTTON**.

THE nervous headache of brain-workers is probably due to a chemical poison circulating in the blood.—**PROF. BLAKIE**.

TYPHOID FEVER has troubled many minds; but Professor A. J. DOWNES declares that the most successful means of combating it consists in the *continued application of cold* to the abdomen, over the lower coils of the ileum and the beginning of the colon.

PILOCARPINE, hypodermically used in ½ grain doses, helped **WALTER BANN** to cure 40 cases of aggravated *erysipelas* in 3 to 5 days. The very first injection reduces inflammation and promotes convalescence.

CALOMEL fumigation is far superior to antitoxin, in the treatment of croup and diphtheria, thinks **DR. BENJ. ELLSON**.

COPPER-HEAD snakes are as poisonous as rattlesnakes; **DR. J. K. CRISSEL**, writes the *Medical World*, saying that he was called in to see a woman, bitten 4 hours previously by a copper-head on her hand. He ligated the arm above the elbow; freely opened the bite with a lancet, and applied a strong solution of *potassium permanganate* to the wound and all over the hand, as also administered some hypodermically. The woman *completely* recovered in 4 hours.

HIRAM J. COON, M.D., cures *epilepsy* by, three times daily, administering a tablespoonful of *mercuric ammonia* solution, made by filling a half-pint bottle half full of the granular salt and filling the rest of the bottle with water.—*Medical World*.

LOCHIA may be promoted by giving fl. ext. *Jaborandi* ʒi x, every 8 hours or they may be re-established by hot fomentations and putting patient under the influence of ipecac and opium.—**S. B. LITTLEPAGE, M.D.**

CREAM OF TARTAR, locally applied or injected urethrally, gave **DR. OTTERI** marvellous success in the treatment of 280 cases of *gonorrhoea*, buboes, chancres and preputial operations.

COCAINE injections into the testes, thinks **S. E. MCCURLEY, M.D.**, are vastly superior to castration in the treatment of enlarged prostate, as they are rapidly absorbed; atrophy the prostate and terminate the production of spermatozoa, without, however, destroying the power of copulation.

FOLLICULAR TONSILLITIS, gives a deal of trouble and appears as the result of a toxæmia produced by the absorption of accumulated material in the lacunæ, and if these be cleaned out and then have peroxide of hydrogen applied to the cavity, as a *quick* and successful cure is made.—**J. C. HOAG**.

PILOCARPINE, hypodermically in ½ grain, may be regarded a specific in *articular rheumatism*.—**DRAPPIER**.

"**SOLID FOOD**, unless ordered in writing by a legally qualified physician, must not be given to infants under 1 year" rules the new French legislature, which provides heavy penalties for delinquents.—*Medical Herald*.

SPARTEINE SULPHATE, in ½ grain doses, is very satisfactory in *exophthalmic goitre*.—**GAILLARD**.

ASAFOETIDA begun with 1½ grain doses, gradually increased to 10 grains and as gradually decreased, removes the tendency to *habitual abortion*.—**WARMAN**.

CITRIC ACID, is praised by **M. PELLISIER** as a remedy in *Gonorrhoea*.

TARTAR, of the teeth can be readily removed by rubbing the encrusted surfaces with a wooden spatula moistened with *trichloroacetic acid*; but this must be done *carefully* as the acid is a powerful escharotic.—**DR. FIERCE**.

SODIUM MONOSULPHITE, 8 grains (or ʒi ss. gramine) daily, rapidly eliminates lead from the system, is devoid of danger and a panacea in *lead colic*.—*Pharm. Record*.

SODIUM CHLORATE, combined with *Aristol*, has been found valuable in *cancer of the stomach*; but needs to be given in large doses to relieve functional disturbances.—**DR. HUGHARD**.

CORRESPONDENCE.

SIR WILLIAM ROBERTS AND THE
OPIUM QUESTION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Shortly after I had looked over Sir Wm. Roberts' medical report on the opium habit, I received the *Indian Medical Record* with your editorial in reply.

I need not say that I was delighted to see it. Were it not for the grave problems connected with the subject one would wish to let the matter rest where it is and allow the report die a natural death. I have come across many medical men since coming to the old country, and I found as a result of the Commission that they in many cases had decided for the present to have no views whatever on the subject. The enquiries of the Editor of the *British Medical Journal* and the conclusions of the medical adviser of the Opium Commission had not brought them to any definite position or made them pro-opiumists, but it had set them wondering why such views were possible. There is no question of "Revenue" to bias the mind, and what they would like to know is why the native of India should be so benefitted by a habit hurtful to all who become addicted to it at home, and whether the secret of the difference is in the native or the country.

Your editorial I handed over to a medical brother the same day it arrived, and he returned it and Sir Wm. Roberts' report with the remark that your reply was conclusive.

Anyone reading Sir Wm. Roberts' report cannot fail to see that the facts are arranged to suit his theories. His notes on the opium habit in children are reading of an entertaining but not convincing character.

The theory runs as follows:—"It is difficult to believe that a practice so widely diffused through all grades of society, and carried on under the direct supervision of the vigilant maternal instinct should have maintained itself so long in credit if it were on the whole and to any appreciable extent injurious."

When one recalls all the barbaric practices which for centuries under the sanction of all grades of society and under the direct supervision of not only ignorant mothers but so-called medical men, and when one reads of many of the practices of savage Africa of the present day in connection with women and children which have prevailed for centuries, it is difficult to believe that any medical man would advance such reasons for the purpose of proving a habit to be beneficial.

Because many men partake daily for years of alcoholic liquors, he would be a rash man now-a-days who would base his defence of the alcoholic habit on this statement. Because not so very long ago many mothers dosed their infants with toddy and gin or alcohol in one of its forms, would any one now venture a word in its favor on this premise?

Because it is a widespread practice throughout certain districts in Rajputana, when a child has been ill for a short time to call in a village surgeon who, as I have seen myself, stretches out the child on the ground and with a red hot iron cauterizes it on many spots over the chest and

abdomen, will any medical man, doctor or student, who tortures to be beneficial, and yet the same surgeon and be advanced for this as for the opium habit in children?

Thus the vigilant maternal instinct? That is true, but more slave to custom. And in India, where the vigilant instinct of the young mother is completely subservient to the judgment and leadings of the mother-in-law, in whose house she generally is, and under whose control she mostly lives, the value of the vigilant maternal instinct becomes so merged in the customs of the family handed down from generation to generation as to be practically valueless. Sir Wm. Roberts was ignorant of the Indian family life, and Sir Wm. Roberts formed conclusions where he was not from his ignorance capable of doing so.

He no doubt felt called upon to issue some sort of a report to satisfy the promoters of the Commission; and all will sympathize with him in the difficulties which surrounded his path. Much of the evidence was bewildering even among pro-opiumists the evidence was contradictory and confusing. Yet no one can compare Sir Wm. Roberts' conclusions with the analysis of the medical evidence which formed the basis and supplied the wording of the medical portion of Mr. Wilson's report without at once falling in with the main portions of the medical views advanced in the report of the latter.

As the accredited medical expert of the Opium Commission, it would have been juster to many medical men and to the readers of the report if Sir Wm. Roberts had dispassionately laid down a fair statement of both sides of the case and left the readers to form their own opinion.

The conclusion which comes uppermost is that there is ample room for personal medical work in connection with the opium habit and many points calling for patient accurate investigation.

Yours, &c., WM. HUNTLY, M.A., M.D.

EDINBURGH, 7th September 1895.

:O:

TREATMENT OF LADY DOCTORS IN THE N.W.P.
TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—May I ask your valuable journal to espouse our cause and bring our grievances before those of the public who would feel disposed to render us material assistance and redress.

Not long back a circular was issued to the effect that Lady Doctors and female medical assistants of all grades, working in the Provincial Branches of the Dufferin Hospitals, should in all matters connected with hospital work consider themselves under the supervision and orders of the Civil Surgeon of their respective stations. We do not shrink our duty nor even dream of deviating from this order; but is the authority who issued the circular aware of the grievances and indignities to which female medical help is subjected, and when the hospitals are officially inspected, how is it that not a single question is asked as to whether the lady doctors are themselves comfortable, or not?

I know of one instance, where, for no offence whatever a female Hospital Assistant was scolded, in the presence of her Assistants and medical establishment, by the Civil Surgeon, who, afterwards finding himself in error, apologized to her privately the next day. Is this practice, and one possibly conducive to encouragingness in work?

The Civil Surgeon does practically nothing of the work actually done by the Lady Doctors, as he has to depend for information on his Assistant Surgeon, who in turn looks upon the compounder, who may, or may not, be honest in reporting. Now if the compounder be not on good terms with the female Hospital Assistant, he brings false charges against her, and, if he be (as often happens) a favorite of the Assistant Surgeon, a bad report goes in against her to the Civil Surgeon, who immediately comes down on her and she has to bear her scolding weekly, if she does not wish to risk her appointment, which is the mainstay of herself and family.

Suppose, however, that she did submit her version of the story to either the Civil Surgeon or to the Inspector-General of Civil Hospitals, how would she substantiate her facts, as it is scarce likely that the menial establishment would risk punishment, or loss of their appointments, by giving evidence against the Assistant Surgeon?

Who will come forward to save the poor Female Hospital Assistant from the dangers that day and night assail her?

Yours, &c., ONE INTERESTED.

LEUKODERMA.

TO THE EDITOR, "INDIAN MEDICAL RECORD,"

SIR,—On page 238 of your Volume VIII A MOFASSALITE wishes to know (a) whether leukoderma is common among Europeans and Anglo Indians; (b) most beneficial line of treatment, and (c) a pigment which would hide the unsightly marks. Having made a special study, of some 16 years, of cutaneous affections, I shall endeavour to answer these questions, and though I write under a *nomme d'plume*, you are at perfect liberty to exchange my card with MOFASSALITE should he desire it.

(a) Yes, I should think so, as 18-28 per cent. of 1034 cases of this affection that I have attended were Europeans and Anglo-Indians. (c) Tattooing and inunction with preparations containing salts of silver, gold, or platinum have been tried; but the effects of these pigments is transitory and in some cases they have led to very untoward consequences. (b) ATMARAM suggests excision of the parts and grafting with pigmentary epithelium; but this method is harsh indeed. Occasionally success has been obtained by external application of iodides and the internal exhibition of the salts of arsenic, iron, galbanum or gold, Indian Madar and some of the higher vegetable oils. Just as any other man I have had my successes and failures but after noting that leukoderma is invariably associated with a greater or less degree of anaesthesia I concluded that instead of the old-school idea of merely "loss of pigment" the affection was really "impaired or deficient pigmentary-cell function" and accordingly reduced the legitimate 66 per cent. of failures to about 9 to 15 per cent. by the following procedure:—The affected parts having been carefully washed with soap and hot water and dried, one, two, or more (if the patient can stand it at one time) of the spots are dry-fomented and one or two drops of *Onchus Ascaridius Occidentalis* rubbed into them. This is repeated, once daily, till vesicles rise, the vesicles are broken down by a final application of castor oil and the sore healed by dressing with *Gynopentauris* solution, of which from

5 to 15 minims are also given, internally, 3 times daily. This operation is absolutely painless and, the sore healing with a perfectly smooth surface, the white area is considerably smaller and the counter-irritation (or stimulation) and alternate healing-up is repeated until the white or pinky-white marks disappear to never return.

Yours, &c., M. D., C. M.

PUBLICATION IN THE LAY PAPERS OF THE NAMES AND QUALIFICATIONS OF HOSPITAL STAFFS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Adverting on the practice of the officials of provincial hospitals advertising the names of the honorary staff, with full academic titles and qualifications, in the lay press, a member of the British Medical Association writes from Grimsby to a contemporary of your journal that the practice is an *objectionable* one that ought to be discountenanced. I wonder what he would say were he out here and glanced his eye across "Surgeon-Lieutenant-Colonel D. GALEN, M.D., M.B.C.S., D.R.H., to the civil charge of All Saints Lunatic Asylum" and such like, in the columns of the lay papers, and it is a marvel to me that with their tremendously strict enactments of medical ethics the British Universities have not found fit to remind the Indian Government that is both unconstitutional and unprofessional for Gazette notifications, of transfers, to contain the military rank and full academic titles of its medical men and otherwise make *ostentatiously* public what really concerns the Department alone and no one else, when a letter, of appointment, or transfer, &c., sent direct to the parties affected, would be more than ample and advertisement of the same is unnecessary. Whereas if advertising is absolute law a notice such as "The Officer in medical charge Khulna Railway will relieve the Officer in medical charge Dera Ghazi Khan" would more than satisfy the law.

Suppose I were to advertise my change of address and, in so doing, append to my name a list of all the qualifications I hold (some *thirty-eight* capital letters) what a racket there would be: (1) The Calcutta folk would terrify me mad. (2) My confreres call me cad, (3) My *alma matres* would probably strike me off their rolls, or severely haul me over the coals; and (4) the General Medical Council would demand inconvenient explanations.

But strange is it not, that the same colleges and medical bodies that would censure me for such above conduct because I am not a Government doctor, have, positively, nothing to say to the Government of India for repeatedly doing what every medical practitioner cannot but stigmatise as *very bad form*?

Yours, &c., NOW OFFICIAL.

THE POSITION OF BUBOES?

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—My attention has, for some considerable time, been attracted to the fact that, in both zones, buboes—excluding sympathetic ones—occur most frequently in the right groin, and for the past six years I have kept notes which I now tabulate, as having reached 150

The position of the ulcer was about equally divided, and as the lesions are too many to have a semblance of regularity, and I am unable to explain the reason, I would feel much obliged if some one else could do so.

150 Cases of Buboes.

| Sex. | Right. | Left. | Both sides. | Suppurated. | Subsided. | Total. |
|--------------|--------|-------|-------------|-------------|-----------|--------|
| Native men | 108 | 9 | 4 | 108 | 15 | 119 |
| Women | 14 | 3 | 1 | 18 | 2 | 19 |
| European men | 10 | 4 | 11 | 24 | 11 | 24 |
| Total | 132 | 16 | 15 | 150 | 28 | 178 |

Yours, &c., ALF. McCABE DILLON, L.M., DUB., L.R.C.S.I., &c.
Kumbhar, 18th September 1895.

THE SEAT OF CHANCER.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Authorities are not unanimous respecting the favorite seat of chancre; but within my 20 years, practice, I have noticed that the most common locality of the primary sore is the furrow behind the glans in the male and in the fourchette, or at the vaginal entry, in females, and I also note that in those persons who have been circumcised or have the foreskin retracted there is almost immunity from phimosis or buboes; whereas in cases where the prepuce covers the glans there is a great tendency to one or other or both of these conditions, either through lymphatic sympathy or from the irritation of the chancrous discharge.

Of 62 cases of genuine chancre that came under my observation I found that (a) 42 were in the furrow behind the glans, (b) 11 on various parts of the glans itself, (c) 6 near the meatus, and (d) 3 near the frenum. The time required for treatment was 16 to 20, 7 to 25, and 7 and 25 days respectively, and no ill results followed classes b, c and d, all of whom were cured with the exception of one case of class d, where the result was unknown.

Of class a however 16 got buboes, 10 phimosis, 1 gangrene of the glans and 15 escaped secondary complications; 23 of these cases were cured, 10 relieved, 3 forewent treatment and in 7 the result is unknown. The phimoses were laid open or circumcised, all the buboes subsided, and the gangrene case had his glans amputated.

Yours, &c., AGIA RAM, C.M.S.

SUKESAS HILL, SHAPUR.

GREENSTICK FRACTURE: HOW TREATED.

TO THE EDITOR "INDIAN MEDICAL RECORD."

SIR,—With any of your numerous readers be so good as to explain whether, in greenstick fracture, the bone should be forcibly straightened to its normal position and the risk taken of a complete fracture or should it be reduced simply and the limb allowed to become a callus, after having taken place?

Yours, &c., SURESHCHANDRA.

GOVERNMENT OF INDIA.

GOVERNMENT OF INDIA.

The most Honorable Order of the Right Honorable Sir, Surgn.-Col. Lionel Dixon Spencer, I.M.S., for services in Waziristan.

To be a Companion of the Distinguished Service Order—Brig.-Surgn.-Lieut.-Col. George McFrieda Davis, I.M.S.

To be probationary Surgn.-Lieut. in the I.M.S.—

Rangoon.—John Stephenson, Frank Wainwright, Walter Barrie Turnbull, Ernest Edwin Whaley, Arthur Leventon, Philip Francis Chapman.

Madras.—Frederick Linton Blackman, Alfred Moore, Edmund Morris Hillington, Thomas Edgar Watson, Charles George Webster.

Bombay.—Alfred Hooton, Arthur Frederick William King, Robert Fraser Standage, Andrew Armstrong Gibbs, Henry Alfred Forbes Knapton.

Brig.-Surgn.-Lieut.-Col. H. T. Brown to officiate on the Adm. Med. Staff of the Army, with the temporary rank of Surgn.-Col., *viz* Surgn.-Col. T. Macneil, Rawalpindi Dist., appointed Chitral Relief Force.

The services of Surgn.-Capt. W. D. Sutherland and H. E. Banatvala are placed at the disposal of the Chief Commr., C.P.

The services of 2nd class Milly. Asst. Surgn. W. Porroster M.B.S., and of 3rd grade Asst. Surgn. A. Williams L.B.A., are placed at the disposal of the Punjab Govt.

Privilege leave is granted as under—Surgn.-Maj. P. A. Wier M.B., I.M.S., 90 days from 18th Oct.

Her I. R. H. the Queen has permitted the following retirements from the service:—

Surgn. Lieut.-Col. J. O. M. McDonnell, M.D., from 29th July; Henry Hyde from 25th May.

Vet., Lieut.-Col. G. Kettlewell, from 19th Feb.

The following promotions are made:—To be Surgn.-Col.—Samuel O'Brien Banks. To be Brig.-Surgn. Lieut.-Col.—G. W. Calthorp, M.D., W. A. C. Roe. To be Senr. Asst. Surgn. with hon. rank of Surgn.-Lieut.—James Kelly, from 2nd Jan.; R. D. Crabbe; and William Hyde. To be Senr. Asst. Surgn. and Hon. Surgn.-Capt.—Thomas Davis; and Geo. H. Campbell. To be Senr. Asst. Surgn. and Hon. Surgn.-Maj.—James Forsyth. To be 1st class Asst. Surgn.—Harry Day; Joseph Brandon, and John Rowley. To be second class Asst. Surgn.—F. G. H. Deeks, N. A. Lemonline, and William G. Marsh.

BENGAL GOVERNMENT.

The undermentioned Asst. Surgn. has been promoted.—James Kelly to be Hon. Surgn. Lieut. from 2nd January.

Second class Asst. Surgn. to be first class Asst. Surgn. Harry Day 15th June; John Rowley from 8th July.

The following Asst. Surgns. are posted as under:—Pranabhat Bannerji and Kedar Nath Madak to the Pres. Genl. Hosp., Calcutta; Nripendra Nath Basu to the Medl. Off. Hosp.; V. M. Carleton to off. as M.O. at the Pandharpur; San Chandra Moumder to have temp. civil med. charge Pubns; Hari Charan Sen to the Plague Hosp. at Gaya; Mohendro Nath Dutt, to civil med. charge Feroz Durg; Mohendro Nath Das to the Pres. Genl. Hosp. Calcutta; Bhogobutty Komar Chowdhury, to the Animal Vaccine Depot, Calcutta.

Surgn.-Capt. W. J. Buchanan to off. as Civil Surgn. Bangalore from 10th Sept., *viz* Surgn.-Maj. G. James on leave.

Surgn. Lieut.-Col. W. F. Murray made over charge of Arrah Jail to Asst. Surgn. Krishna Gopal Mitter on 14th Sept.

Surgn.-Maj. A. James made over charge of Muzaffarpur Jail to Surgn.-Maj. F. S. Pack on the forenoon of the 10th Sept.

Privilege leave is granted as under:—

Asst. Surgn. Gobind Chander Chatterjee, from 4th to 22nd Oct. 1894; Surgn. Maj. G. James, 20 days from 18th Sept. 1895; Milly. Asst. Surgn. V. M. Carleton from 15th Sept. to 1st May 1895.

The following medl. charge was held:—

Asst. Surgn.—Kedar Nath Madak of Pres. Genl. Hosp. from 15th to 22nd Oct. 1894; Nripendra Nath Basu of civil station, Chhannagaon from 1st May 1895.

INDIAN GOVERNMENT.

The following have been granted the following offices:—
Surgn.-Maj. E. T. Parry, 99 days from 22nd August: B. Doyle, 99 days from 30th August.

The following have accepted charge as under:—
Surgn.-Capt. A. T. Macdonald of civil medical duties Madras on 22nd August.

The following appointments are made:—
Surgn.-Lt. C. E. Prall of 86th Sikhs, to offg. Civil Surgn. Peshawar from 25th Aug., vice, Surgn.-Maj. R. Doyle on leave.

Asst.-Surgn. Malik Jowala Sahai to offg. Civil Surgn. Calcutta, from 22nd Aug. vice, Surgn.-Maj. L. T. Young on leave.

PROMOTIONS.

To be Brig.-Surgn. Lieut.-Col.—William Alexander Crawford Bn. from 25th March 1893.

Her Majesty has sanctioned the retirement from the Service of Surgn. Lieut.-Col. James O'Malley MacDonnell, M.D., from 29th July 1893.

MADRAS GOVERNMENT.

Privilege leave is sanctioned as under:—

Surgn.-Maj. G. L. Walker from date of return to duty of Opde-Surgn. Lieut.-Col. W. Price, to 1st Oct.

Mr. C. A. Lafrenias to offg. Civil Surgn., Tellicherry, vice Surgn.-Capt. D. Simpson, M.B.

BOMBAY GOVERNMENT.

The following are nominated Commrs. of the Malcolmpeth Municipality in the Satara Dist. from 1st Oct.—Surgn.-Maj. C. Monks, Supdt. Abraham Shalom, Hosp. Asst.

Asst. Surgn. Ramchandra Shivaji Porodi, L.M.S., on general duty from 24th Aug.

Asst. Surgn. Mancherji Jamsaji Mistri and Surgn.-Capt. John Blackburne Smith delivered over and received charge of Shikarpur Prison on the 28th Aug.

Surgn.-Maj. T. R. Mulrooney, M.D., resumed charge as Civil Surgn. of Amritsar on 31st Aug. 1893, relieving Asst. Surgn. Sodhi Karam Singh.

Surgn.-Capt. Clark, M.B., Offg. Civil Surgn., Lahore, has obtained furlough to Europe for 2 years, with effect from the 3rd Nov.

Surgn.-Capt. C. T. Hudson assumed charge of civil med. duties of Kohat District on 6th Sept. 1893, relieving Surgn.-Capt. F. R. Orrard.

CENTRAL PROVINCES GOVERNMENT.

The undermentioned Asst. Surgns. are directed to do duty under the Civil Surgns of the districts bracketed against their names:—

Mittra Lal Bosaik and S. N. Sircar (Nagpur).

The undermentioned I.M.S. Officers are placed at the disposal of the Chief Commr.—Surgn.-Capt. W. D. Sutherland and H. E. Babatvale.

The undermentioned Civil Hosp. Assts. are transferred:—*First Class.*—Bin Mahmood to Central Jail Hosp., Bampur; Abid Hussain to be under the orders of the Civil Surgn., Jubbalpur; Bagherwarh Tukaram to the Main Diapp. Quana, *Second Class.*—Anandwin to the Jail and Police Hosp., Mandla; Musak Parash to the Central Jail Hosp., Jubbalpur. *Third Class.*—Mowrar to be under the orders of the Civil Surgn. Warkeha; Davedramath Bajerji to the Jail Hosp., Narainpur; K. Ramiah Malik to be under the orders of the Civil Surgn., Nagpore.

R.-W. F. AND OUDH GOVERNMENT.

The undermentioned offrs. are granted priv. leave:—Surgn. Maj. J. C. Parry, 99 days from 1st Oct.

Surgn.-Capt. H. W. Thomas, from 13th to 32nd Aug.

The following Asst. Surgn. has been transferred:—

Mr. P. Thomas, from Surgn. Diapp. to Sect. Diapp., Dehra

Doon.

Mr. J. C. Parry, M.D., has been posted to the 2nd.

BURMA GOVERNMENT.

PROMOTIONS.

To be first grade Asst. Surgn.—Durgu Das Bhattacharya from 1st May. To be first grade Hosp. Asst.—Srinivasan, from 2nd July. To be second grade Hosp. Asst.—T. K. Pillay from 29th April.

The Shwegyin Municipal Committee elected Mr. D. P. P. first grade Hosp. Asst. to be their Vice-President, vice Mr. Asst. Surgn. H. Wells, resigned.

The following assumed charge as under:—

Surgn.-Maj.—C. B. Bandle, M.B. of Jr. Civil Surgn. and M. O. Mily, Police Hosp. and Sunda Lunatic Asylum on 7th Sept. Surgn.-Capt.—C. N. Boudier of Thapaymyo Civil Surgn. and of Thapaymyo Central Jail on 11th Aug. First grade Hosp. Asst.—Shank Hyder Ali of Tenga Civil Hosp. on 21st Aug.; Syad Mahmood Abbas Bader of Sengar Police Hosp., Lt. Ohindwin Dist., on 23rd Aug. Second grade Hosp. Asst.—Mang Kho of Civil Diapp., Yangon, Magwe Dist., on 16th Aug. Abdul Wahid of Ry. Diapp., Myittha, Kyaukse Dist., on 3rd Aug.; Tijamal Hussain of Outpost Police Hosp., Mohayin, Katha Dist., on 21st Aug.; U. O. Chuckerbatty of Police Hosp., Bhamo 4th Sept.; Abdul Sattar of Police Hosp., Monak, Ruby Mines Dist., on 17th Aug. Third grade Hosp. Asst.—Anand Bhandu Mukerji of Mu Valley State Ry. Diapp., Mohayin, Katha Dist., on 11th Aug.; K. C. Pall of Civil Diapp., Thama, Khan, S. Shan States, on 11th Aug.; T. A. Ramaswamy of Police Hosp., Pokokku, on 15th Aug.; Bisco Charn Das of Police Outpost Hosp., Tagaung Ruby Mines Dist., on 20th Aug.; Bisco Mohun Bose of Police Hosp., Bhamo, on 23rd Aug. and thence to Shwebo Police Outpost Hosp. on 3rd Sept. Sharfuddin of Ry. Diapp., Insein Hanthawaddy Dist., on 6th Sept.

Medical charge was relinquished as under:—

Hdqd. Surgn.-Lieut.-Col. H. Johnstone, M.D., of Jail Civil Surgn. and M. O. Mily, Police Hosp., Bhamo, on 7th Sept. Surgn.-Maj. C. B. Bandle, M.D., of Thapaymyo Civil Surgn. on 30 Aug.; R. E. S. Davis, M.D., of Supt. Bhamoon Lunatic Asylum on 7th Sept.; C. B. Bandle, M.D., of Thapaymyo Central Jail on 30 Aug. First grade Hosp. Asst. C. Poornocawmy Modelar of Ry. Diapp., Insein, on 8th Sept. Second grade Hosp. Asst.—Abdul Wahid of Bhamo Police Hosp. on 19th July; Ram Lal of the Civil Diapp., Genangyang, Magwe Dist., on 18th Aug.; M. Deraswamy Pillay of the Ry. Diapp. of the Mohayin, Katha Dist., on 11th Aug.; U. O. Chuckerbatty of the Police Outpost Hosp., Shwegu, Bhamo Dist., on 3rd Sept.; Abdul Sattar of Mily Police Hosp., Bhamo on 1st Aug.; Pandit Shankar Das of the Civil Hosp., Thama, S. Shan State, on 11th Aug.; Tijamal Hussain, Mily Police Hosp., Katha, on 17th Aug. Third grade Hosp. Asst.—K. C. Pall of Telegraph Party, Kengung B Survey, Fort Stothman, Shan States on 4th Aug.; Bisco Charn Das of Police Hosp., Monak, Ruby Mines Dist., on 17th Aug.; Bisco Mohun Bose of Shwebo Police Hosp., on 4th July and of Bhamo Police on 3rd Sept.; Sharfuddin of the Genl Hosp. Bhamo on 4th Sept.

G. O. C. C.

The following A. M. S. officers having completed their tour of foreign service are placed on troopship service, on the homeward voyage:—

Bygd.-Surgn. Lieut.-Col. H. T. Brown, M.D., M. Bacc, A. A. Macrobitt, M.B.

Surgn. Lieut. Col.—G. Curry, W. Doorman, G. T. Langridge, S. M. Bismarck, J. Martin; R. H. Quill, M.B.

Surgn.-Maj.—H. Leader, H. E. W. Barrington, T. B. Moffit, G. F. A. Myrthia, J. Harman, W. Dugdale, L. W. Swabey, T. E. Nodding, I. B. Emerson, A. W. Carlson, M.B. W. T. Johnston, M.D., B. O. Ousack, W. D. A. Cowan, A. F. Hart, M.B. E. Butt, E. H. Myrie, M.D., A. E. J. Oroly, M. L. Mannell, R. F. Adams, M.D., G. G. D. Meese, J. A. Macdonald, T. A. Bisco, G. W. Robinson, G. F. Fryden, C. B. Woods, M.D., W. Kenya, H. A. H. Charlton, J. Watson, M.D., A. O. Goughan, M.B.

Surgn. Capt.—H. Kelly, M.D., E. J. D. Hill, J. W. Cocherill, W. L. Gray, M.B., E. G. Brown, J. W. Giffen, M.D.

The following have posted in the Hindustani language:—Surgn.-Capt. F. W. Brown, I.M.S., the lower standard and Surgn.-Capt. W. G. Friedman, the elementary.

ORIGINAL ARTICLES.

THE IMPORTANCE OF RESPIRATORY AFFECTIONS IN THE MORTALITY OF NORTHERN INDIA.*

By SAIG-SESON LIMUT, COL. THOMAS-HOLDEIN.

RENDLEY, C.I.E., I.M.S.,

Residency Surgeon Jeypore.

As I have no doubt that many papers will be read at the Congress on rare diseases or on those peculiar to the tropics, I should like to draw attention to the even more urgent necessity of carefully studying the common affections which are responsible for the deaths of large numbers of people, and especially to the inadequacy of our health statistics to show what are the real causes of mortality in India, and, particularly in the Northern Provinces. In the general returns, which are published by authority, no deaths are attributed to respiratory affections, whereas the death-rate from fevers is stated to be enormous. No doubt it is, but I believe that, in a large number of cases, the predisposing, if not in many instances, the true cause of death, is some disease of the lung, which is generally either pneumonia or pleurisy.

My principal reason for coming to this conclusion is that in the *post mortem* room in Jeypore, in a very large number of bodies, old and extensive pleuritic adhesions of one or both lungs are found, and persons who are supposed to have died from malarial fevers are discovered to have really suffered from pneumonia or pleuro-pneumonia. Between January 1888 and August 1894, 336 bodies were examined at the Mayo Hospital in Jeypore, and out of these, in 129 cases, one or both lungs were adherent to the chest wall, or showed the characteristic appearances of pneumonia of one or both lungs. Nearly all the bodies were those of suspicious cases, or of poor persons, which had been found by the police, or individuals who had been admitted to the hospital when in a moribund condition.

In 102 cases of death by drowning there were considerable pleuritic adhesions in 18. In many of the 129 cases referred to, that is, in nearly 38.4 per cent of the whole number of bodies examined, the signs of old lung-disease were very marked. In the eleven year period,—1882 to 1892,† 10,202 persons were treated in the Mayo Hospital in the in- and out-patient departments for disease of the respiratory system. The total mortality, all in the in-patient wards, was 182 or 1.78 per cent, and nearly all the deaths were due to pneumonia. Out of 935 cases of pneumonia there were 93 deaths or 9.94 per cent., which may be taken, I think, to be a very small mortality, as nearly all the cases, almost indeed without exception, were of an asthenic type, and, as a rule, fatal, within a short period of admission, before the effects of good diet, care, and medical treatment could declare themselves.

It is extremely rare for us to see a case in which the cough is dry, nor is the cough very troublesome, though there may be pain in the chest. The expecto-

ration is generally of a rusty brown appearance, and is not very profuse. The sputum is rarely bloody, and brown in a bad case, and often contains a lot of mucus, acts in, with, as a rule, in fatal cases, paralysis of the sphincters and diarrhoea, sometimes accompanied by swelling of the feet and albuminuria. In some cases there is gangrene of the lung, and in fatal cases, grey hepatization or suppuration of the lungs are observed. The pulse is nearly always very feeble and often irregular; the temperature is rarely very high. If it is, I generally consider it as showing a malarious tendency, and give with success several five or ten-grain doses of quinine.

The treatment recommended is a purge for the initial constipation; good and nourishing light diet (milk or soup) at regular intervals, especially during the night; warmth; stimulants; ammonium carbonate gr. v with decoction of cinchona one ounce, every 4 to 6 hours, and run, if necessary; poultices are not essential; antipyretic for high temperature is but rarely used on account of its depressing action.

Many patients are weakly pilgrims, who catch chills from the open windows of the third class railway compartments in Rajputana, from night travelling.

If a man comes into hospital at an early stage the tendency is, under these simple measures, always towards recovery, although the majority of the applicants are extremely feeble and underfed. The worst cases in these respects are those of pilgrims who fall ill on their way to their homes from distant shrines. I think the exposure at night in the third class railway carriages, in Rajputana, is also a cause, not only of cases of lung inflammation but also of other disorders.

There are only wooden sunshade windows. I think glazed windows should be provided in a certain number of the railway carriages, if not in all. They might be removed in summer.

The people do not apply at the dispensaries if they are suffering from slight coughs or a little fever, and yet out of 1,307,481 new cases that were treated at nine dispensaries in the Jeypore State from 1875 to 1892, and in eight, from 1884 to 1892, no less than 75,453 or 5.7 per mille of all the patients suffered from respiratory affections, whereas the figures for malarial fevers were 181,175 and 138,51, respectively, or less than two and half times as many.

These figures show the existence of a great amount of lung-disease which, I find, is most prevalent in Jeypore in the following order of months: March, December, April, November, February and October, and least in June, July, September, August, May and January.

I find that in 1892, 106.77 per mille of all the patients who were treated in the Rajputana Jails were entered under the heads "Lung Diseases" and "Other diseases of the Respiratory System."

In the eleven year cycle, 1882—1892, there were in the same jails 5,276 cases of respiratory affections, excluding phthisis, in 83,759 total sick or at the rate of 34.95 per mille.

There is clearly the factor of overcrowding, and may come in, but these statistics show a large amount of lung disease.

* Being presented before the Indian Medical Congress and sent to the Press for publication.

† The following table gives an indication as to the amount of the mortality.

RESPIRATORY AFFECTIONS.

THE PREVALENCE OF RESPIRATORY AFFECTIONS IN THE MORTALITY OF NORTHERN INDIA.*

By SAHJ, SENIOR LIEUT.-COL. THOMAS-HOLBEIN.
HARLEY, C.I.E., I.M.S.,
Residency Surgeon Jeypore.

As I have no doubt that many papers will be read at the Congress on rare diseases or on those peculiar to the tropics, I should like to draw attention to the even more urgent necessity of carefully studying the common affections which are responsible for the deaths of large numbers of people, and especially to the inadequacy of our health statistics to show what are the real causes of mortality in India, and, particularly in the Northern Provinces. In the general returns, which are published by authority, no deaths are attributed to respiratory affections, whereas the death-rate from fevers is stated to be enormous. No doubt it is, but I believe that, in a large number of cases, the predisposing, if not in many instances, the true cause of death, is some disease of the lung, which is generally either pneumonia or pleurisy.

My principal reason for coming to this conclusion is that in the *post mortem* room in Jeypore, in a very large number of bodies, old and extensive pleuritic adhesions of one or both lungs are found, and persons who are supposed to have died from malarial fevers are discovered to have really suffered from pneumonia or pleuro-pneumonia. Between January 1888 and August 1894, 336 bodies were examined at the Mayo Hospital in Jeypore, and out of these, in 129 cases, one or both lungs were adherent to the chest wall, or showed the characteristic appearances of pneumonia of one or both lungs. Nearly all the bodies were those of suspicious cases, or of poor persons, which had been found by the police, or individuals who had been admitted to the hospital when in a moribund condition.

In 102 cases of death by drowning there were considerable pleuritic adhesions in 18. In many of the 129 cases referred to, that is, in nearly 38·4 per cent. of the whole number of bodies examined, the signs of old lung-disease were very marked. In the eleven year period, 1882 to 1902, 10,302 persons were treated in the Mayo Hospital in the in-patient and out-patient departments for disease of the respiratory system. The total mortality, all in the in-patient wards, was 182 or 1·78 per cent., and nearly all the deaths were due to pneumonia. Out of 935 cases of pneumonia there were 23 deaths or 2·45 per cent., which may be taken, I think, to be a very small mortality, as nearly all the cases, almost indeed without exception, were of an atrophic type, and, as a rule, fatal, within a short period of admission, before the effects of good diet, care, and medical treatment could declare themselves.

It is therefore very far from being a case in which the disease is very rare, or in the cough very troublesome, though it may be felt in the chest. The "expecto-

torious quantity of a rusty brown sputum, and a very profuse. The sputum is rarely bloody and brown in a bed-cough, and often consists of a lot of shag, sets in, with, as a rule, in such cases, paralysis of the sphincters and diarrhoea, sometimes accompanied by swelling of the feet and oedema. In some cases there is gangrene of the lung, and in fatal cases, grey hepatization or suppuration of the lungs are observed. The pulse is nearly always very feeble and often irregular; the temperature is rarely very high. If it is, I generally consider it as showing a septic tendency, and give with success several five or ten-grain doses of quinine.

The treatment recommended is a purge for the first constipation; good and nourishing light diet (milk or soup) at regular intervals, especially during the night; warmth; stimulants; ammonium carbonate gr. v with decoction of cinchona, one ounce, every 4 to 6 hours, and run, if necessary; poultices are not essential; antipyretic for high temperature, is, but rarely used on account of its depressing action.

Many patients are weakly pilgrims, who catch chills from the open windows of the third class railway compartments in Rajputana, from night travelling.

If a man comes into hospital at an early stage the tendency is, under these simple measures, always towards recovery, although the majority of the applicants are extremely feeble and underfed. The worst cases in these respects are those of pilgrims who fall ill on their way to their homes from distant shrines. I think the exposure at night in the third class railway carriages in Rajputana, is also a cause, not only of cases of lung inflammation but also of other disorders.

There are only wooden sunshade windows. I think glazed windows should be provided in a certain number of the railway carriages, if not in all. They might be removed in summer.

The people do not apply at the dispensaries if they are suffering from slight coughs or a little fever, and yet out of 1,307,481 new cases that were treated at nine dispensaries in the Jeypore State from 1875 to 1892, and in eight, from 1884 to 1892, no less than 75,463 or 5·7 per mille of all the patients suffered from respiratory affections, whereas the figures for malarial fevers were 161,175 and 188,51, respectively, or less than two and half times as many.

These figures show the existence of a great amount of lung-disease which, I find, is most prevalent in Jeypore in the following order of months: March, December, April, November, February and October, and least in June, July, September, August, May and January.

I find that in 1892, 105·77 per mille of all the patients who were treated in the Rajputana Jails were entered under the heads "Lung Diseases" and "Other diseases of the Respiratory System."

In the eleven year cycle, 1882-1892, there were in the same jails 5,375 cases of respiratory affections, including phthisis, in 22,759 total admissions, or at the rate of 24·05 per mille.

Now, possibly, the factor of overcrowding may come in, but I think it is a large amount of lung disease.

mixture; sometimes, to do the service of hops and camomile's bitter taste; grapes of paradise and cayenne pepper to give pungency; cardamom, caraway, and similar other spices to give flavor; liquorice, treacle and honey to give color and consistency. But the liberties taken with wines which admit of large foreign admixtures are great indeed and port, sherry, and champagnes do not always mean what their names imply. The common adulteration in port and sherry, is spirit, which is not always the product of vinous fermentation, but may be corn, potato or, sometimes, beet-root spirit. The following story anent the manufacture of port wine tells an instructive tale:—

"A friend of mine," says the writer, "who was staying in Reading, during the militia manoeuvres had occasion to go into the backyard of one of the hotels, where he saw a huge caldron, in which an old croon was stirring a black mixture looking like a compound of blacking, black-berries and sloes, plucked from the neighbouring hedges. What are you brewing there, my good woman? asked my friend. "Port wine for the Berkshire Militia," pertly replied the old hag, who kept stirring up the mixture with a thick stick.

Similar adulterations take place in sherries, as illustrated by the following:—For cold brown sherry, 20 or 30 gallons of unf fermented juice are boiled in earthen vessels to one fifth of its bulk, when it looks and tastes like treacle and is turned into a cask, containing more *must*, here it ferments, and the result is a very full luscious wine which is harmless compared with any one of the following three receipts.

1st.—Forty-five gallons of cider, 6 of brandy, 8 of port-wine, 2 gallons of sloe pressed in, 10 gallons of the liquor pressed off. If the color is not good, tincture of red sanders or cudbear is to be added. This is bottled and sold as port.

2nd.—Spanish wine 1,529 gallons, Fayal wine 544 gallons, French wine 4,472 gallons, Cape wines 689 gallons, Portugal wine only 117 gallons, and 154 gallons of brandy; the result obtained being 7,525 gallons, minus 8 gallons loss, which is made up with water and the, grand result of 7,533 gallons of port wine thus manufactured; was intended for exportation.

3rd.—All the refuse wine, red or white, old samples, heel-tops of bottles, and half tasted glasses, are thrown into the collecting barrel, (just as the cook throws any kind of meat and soup-liquor into his stock pot), and, with the addition of a little spirit and coloring matter, are sold as very good eighteen-shilling port.

Our Radha Bazar dealers, trodding in the footsteps of their European prototypes, have learnt a bit of the art, and can turn out sherry of their own mixing together:—

Juice of pine-apple peel, fatty matter of rotten plantains, of the *champee* species, treacle, rum and coloring matter. These sell at any price from Rs. 5 to 18 a dozen, according to the taste or the experience of the buyer.

Here is another general receipt for making sherry, port, and ginger wine:—Egg's eggs, sugar, ginger and rum, rummaged together with coloring matter made from burnt sugar or aspen wood, according to demand. These sell at 1/2 anna and 1 rupee a bottle. Some other liquors are also illegally manufactured, like in a mixture of orange, jack-fruit and plantains with rum, made at home. Vendors

also use grapes, citrons, peaches, and other fruits, which latter contain factors, to strengthen the drink.

It is my first conviction that intemperance has a general, while tendency to add to the number of our criminal population; as many of the most hideous crimes, which the preparators would have never dreamed of in their sober moments, are committed while under the influence of liquor. This is capable of satisfactory demonstration, but I regret that the manner in which criminal statistics are now furnished does not admit of this information being correctly given.

—30—

ON INFECTIOUS PNEUMONIA.*

By SURGEON-MAJ. A. DUNCAN, M.D., F.R.C.S., I.M.S.

Residency Surgeon, Jajpore.

In this paper I propose to consider briefly the nature of an epidemic of pneumonia which came under my observation, and which afforded a striking example of the specific infectious nature of the malady. In my student days, the idea of pneumonia being a specific fever with its local manifestation in the lung was not advocated. Since that time, however, much evidence has been brought forward that such is its nature. The first indications pointing in this direction arose from the discovery of a bacillus. Undoubtedly the savant who first discovered this was the late Dr. FRIEDLANDER. In 1877 I was working in the laboratory of Professor BROOKINGHAUSEN, to whom Dr. FRIEDLANDER was Chief Assistant, and I remember, in conversation with him, his telling me that he was on the track of a bacillus. I do not propose to enter into the subsequent researches on the micro-organism beyond merely recalling some of the names, such as Weichselbaum, Fraenkel, Talamon and many others who have worked at this subject. The bacillus of Fraenkel is however claimed at the present day to be the essential micro-organism.

I pass on now to the history of the epidemic I noted. On November 25th, 1885, the 23rd Pioneers arrived at Umballa from the Pishin Valley. From November 25th, 1885, to April 26th 1886, thirty-three cases of pneumonia occurred. By months they were thus distributed: four in November, nine in December, five in January, five in February, five in March, five in April. Many surmises as to the cause of the affection were held. First, that the regiment was inadequately clothed, and that the men caught cold. Now the regiment was, in fact, one of the best clothed in the Native Army. In addition to their ordinary dress, each man had been provided with a thick sailor's jersey. Secondly, it was held that the regiment had returned from Pishin broken down in health. The following was the daily admission rate for the regiment from 1881 to 1885: In 1881, 39.65 per 1,000; in 1882, 37.29 per 1,000; in 1883, 27.43 per 1,000; in 1884, 18.55 per 1,000; in 1885 31.41 per 1,000; in 1886, 12.32 per 1,000. At first sight the admission rate for 1885 seems greatly in excess of that for 1883 and 1884, but a more minute examination showed the following facts: The great bulk of the regiment was in the Hospital from the 1st to the 15th

* Being a paper read before the Sanitary Conference at Jajpore, in March 1886.

From April 18th to November 16th the regiment was in the Upper Valley. From the latter date it was in the Lower Valley, reaching this place on November 16th. Now the rate of the head-quarters was 25-74 from January 1st to April 18th was 25-74 from April 18th to November 26th, 19-21; from November 27th to December 31st, 39-40. Hence the large bulk of admission occurred after the regiment had returned from Pishin, whilst in Pishin the admissions were only slightly in advance of those of the preceding year. *Thirdly*, a white fog that prevailed in the West in January was held in some way to have caused the disease, much in the same way as a yellow fog was evoked to account for the cholera by some authorities in Egypt in 1868. Unfortunately, however, for this foggy idea, the pneumonia continued when the white fog had disappeared, much in the same way as cholera has appeared when there has been no yellow fog. *Fourthly*, it might have been due to the cold from December to February. Cold, however, could not have caused the cases later. The temperature was taken in my hospital three times daily. Not to weary you with the tables I will merely state the temperature found at noon. In March it ranged from 71° to 80°F. In April from 75° to 94°F.

As cases still continued to come into hospital, I determined to treat them as infectious. Under my advice the O. C. had the lines vacated and the men placed under canvass. The lines were then disinfected with sulphurous acid gas, for six hours, every aperture being closed up, and on the day following the fumigation they were freely ventilated. On the third day the lines were re-occupied. By April 14th, all the lines, with the exception of those of the band, had been disinfected. On April 14th, case thirty-one, that of a musician, occurred. On the 15th the band went into tents. Two cases subsequently occurred on April 18th in the married lines: one on April 26th in the band lines. Both these cases occurred nine days after the lines were re-occupied, or eleven days, after they had been vacated for disinfection. But if pneumonia be a specific infectious fever, it will have a period of incubation. This period it may be not too much to assume may be as long as eleven days, and thus the disease may have been caught before the lines were disinfected. This theory receives support from the fact that during the same month measles had been present in the married lines. Now, subsequent to the disinfection, three cases of measles occurred, two on April 17th in lines disinfected on the 13th, and a third within a week from the disinfection. The incubation period of measles is stated to range from 7 to 21 days. Hence it is probable that all these cases were beginning, as regards incubation, before the lines were disinfected.

After June 23 the epidemic ceased.

I now propose to offer some observations on this epidemic, and to put forward the reasons for considering it to have been not merely a local inflammation of the lung:—

1. Rate of appearance of the Physical Signs.—There would probably have been some uniformity in the date of appearance of the physical signs had it been only a local inflammation of the lung. The physical signs

surely should appear on the first day if the fever had been local. But in 25 cases they appeared in the following manner:—In 5 on the 2nd day; in 7 on the 3rd; in 3 on the 4th; in 4 in 1 case on the 5th, while in 3 cases the on the 5th; and date was not noted.

2. Different conditions of the lung present on the return to the normal temperature.—If the pneumonia had been a simple local inflammation then with the return to the normal temperature the local condition of the lung should have been generally more or less identical. But in twenty-two cases in which the condition was accurately noted when the temperature fell to the normal—

In 8 cases it was in the 1st and 2nd stages.

In 1 case in the 1st, 2nd and 3rd stages.

In 3 cases in the 2nd stage.

In 10 cases in the 2nd and 3rd stages.

In 5 cases in the 3rd stage.

If the affection had been merely a local one then on the return to the normal temperature the lung should quickly be found to have cleared up. But—

In one case nine days after the return to the normal temperature, the first and second stages were found to be present.

In six cases, the signs of the second stage were present, three, four, seven, eight and fourteen days after the return to the normal.

In one case, those of the second and third stages were found eleven days after the return.

In ten cases, signs of the third stage were found on the second, third, fifth, sixth, seventh, eighth, ninth, twelfth, sixteenth and nineteenth days. If, however, we consider the lung affection merely as local expression of a specific fever, then there is no necessity for it to have ceased at the return to the normal. Thus Peyer's patches are not normal in enteric when the temperature becomes so.

4. There were cases of exceedingly high temperature with no corresponding extent of lung affection.—Thus in one case only the lower lobe was affected, yet the temperature reached 106.4°. In another where only one lobe was affected the temperature reached 106.8°F.

5. In cases where the second lung became affected secondarily to the first had there been merely local inflammation, then a second rise of temperature should have taken place. But cases occurred where, although the temperature had fallen to normal, it remained so, notwithstanding the second lung became subsequently inflamed or where a rapid fall of temperature occurred coincidently with the onset of inflammation in the second lung.

Such then are a few of the arguments that concur in supporting the idea that this epidemic was one of a specific fever, having the inflammation of the lung merely a local phenomena.

Pneumonia has frequently occurred in epidemics in the North-Western Frontier. The idea that cold especially predisposes to pneumonia was conclusively proved to be erroneous by Dr. SARGENT of America. In a paper published in the *American Journal of Medical Science* for July 1892 he showed the disease to be more

frequently met with and more common in warm than in cold climates, and in hot than in warm climates, shewing a gradually increasing ratio from the Poles to the Equator. That pneumonia, other things being equal, increases uniformly in frequency the nearer we approach the tropics. Other relations with the tropics are found to exist, e.g., a higher death-rate. Statistics for warm climates shew an average 1.70 death per 1,000, whilst for temperate zones the ratio is 1.31 per 1,000. These facts fully dispose of the old notion of pneumonia being a local affection due to cold. With these few brief remarks I bring this history to a close.

:o:

PATHOLOGICAL AND ETIOLOGICAL REMARKS ON THE PYREXIAL STATE.

By SURGN.-CAPT. PATRICK HERIE, M.D., F.R.S.E.,
F.R.C.S.E., D.P.H. (Cantab.)

Lecturer on Medicine and Pathology, Hyderabad
Medical School.

THE ancient yet important theory of all fevers being due to the access into the system of some infective material which, multiplying within the body, produces the pyrexial phenomena, still holds with many pathologists, and in a series of lectures like these demands particular attention, even from the modern point of view.

Ptoinaïnes are certain toxic substances, resembling our vegetable alkaloids, which are produced during the process of putrefaction. GANTIER successfully inoculated lower animals with ptoinaïnes found in the bodies of persons, who died of pyæmia, and also noticed that these substances could combine with acids to form a series of salts, without losing their toxic properties. From decomposing yeast BERGMANN and SCHMIEDEBERG isolated a crystalline poison, which, injected into the subcutaneous tissue or venous circulation of animals, produced well-marked symptoms of septic intoxication, the intensity of which varied with the amount of the substance injected. From macerated dead bodies and from putrid meat infusions ZULZER and SONNENSCHNIG obtained small quantities of a crystallizable substance exhibiting alkaloidal reactions and having a physiological action, like atropine, of dilating the pupil, paralysing the muscular fibres of the intestine and increasing the pulse rate. No discovery, perhaps, attracted such universal attention as PASTEUR's micro-organism theory (1859) of fermentation, which theory was confirmed by LEMAIRE's observation, that as all fermentative changes, in fluids, are suspended by the addition, to the fluids, of phenic acid, fermentation must be due to living organisms. Next came the carefully conducted experiments of SIR JOSEPH LISTER, shewing that if air be passed through a filter, before coming in contact with organic fluids placed in an open vessel, with the mouth of the vessel so arranged that dust cannot reach the fluid by gravitation, it (i.e. air) is deprived of its action towards inducing the putrefaction of organic substances.

In former years it was held that the heat generated in inflamed areas was the sole cause of the pyrexial state in local inflammations. This, however, is only apparent; for although the outer parts of the skin over an inflamed part seem warmer, owing to the dilatation of the

vessels (rubor) and the consequent acceleration of the blood-stream in the inflamed part, as well as to the presence of heat-conducting fluids in the swelling, still it is not really warmer than the rest of the body; as the injury done to the tissues and cells must necessarily lower their vitality, and as metabolism is one of the factors of vital manifestation, it is lessened instead of being increased.

ANGERER and EDELBERG demonstrated that fever occurs after transfusion, if the transfused blood contain fibrin ferment. SCHMIEDEBERG attributes fever to the presence of another blood ferment (*hystoxym*).

BERGMANN and ANGERER's researches shew that a fever, resembling fermentation fever, can be artificially produced, in animals, by intravenous injections of pancreatin, pepsin and trypsin; as the albuminoid substances in excess in the blood undergo oxidation by the action of a ferment, and the chemical changes thus brought about elevate the temperature, while the products of oxidation are eliminated through the kidneys. RIEDAL found, in many cases of simple subcutaneous practice, albumen in the urine during the first three or four days, and the urine always contained brown masses of broken-down red blood corpuscles. After transfusion of blood WOOD MULLER invariably found a considerable increase of urates in the urine, and that the fever consequent on a septic infection is probably due to the foreign substances destroying the red and white corpuscles in the blood and generating fibrin ferment.

With regard to the etiology of fever resultant on traumatic injuries, certain heat-generating bodies, formed at the seat of inflammation, are absorbed into the blood and carried through the body, where they may act as poisons, and in this way set up thermogenetic chemical changes, resulting in fever.

Septic intoxication produced by the absorption of a pre-formed toxine or ferment, whose maximum effect is exerted as soon as it gains access to the circulation, and decreases and disappears with the arrest of further supply, and the elimination of the septic material from the circulation. *Septic infection*, on the other hand, occurs as a result of the accession to the circulation of living micro-organisms which multiply with great rapidity in the blood,—a circumstance which imparts to this form of septicaemia its progressive character.

Septic intoxication is produced either by the absorption of fibrin ferment, or the products of putrefactive bacteria—an *enzyme* or a *ptoinaine*.

The essential causes of septicaemia, therefore, are not always the same. This morbid condition represents a general pyrexial state, brought about by absorption from a local focus of various toxins whose access to the circulation is succeeded by a complexus of clinical phenomena, and different microbes having been cultivated from septic patients, it would seem that this disease can be produced by any of the microbes having the capacity of producing a sufficient quantity of ptoligistic ptoinaïnes to give rise to septic intoxication.

Fermentation fever, which is known by several names. [Thus, fermentation fever (BERGMANN), after-fever (BILROTH), septic fever (VOLKMAN), resorption fever] the general pyrexial phenomena are caused by the absorption of the products of septic tissue necrosis. The temporary fever appearing soon after an injury or operation is caused by the absorption of septic

pyrogenic substances which produce pyrexia. BEBOMANN observed this after intravenous injection of a solution of salt. KASNER, after transfusion of blood of healthy animals, and BEBOMANN, STRIKES ALBERT, and BILLROTH after intravenous injections of a considerable variety of materials, including water in which fine flour or finely-pulverized charcoal, were suspended. VOLKMAN and GENZMER observed a rise in temperature in patients soon after the operation was completed, and when the wound remained aseptic throughout, and hence called this form of fever aseptic fever.

Accepting the reactionary theory of surgical fevers, there should be practically no fever after small wounds or slight injury, and in cases of severe injury there should be high fever, lasting for a long period, and between these extremes there should be a range of temperature from a very slight to a very great rise, commensurate to the size of the wound; so that immediately on seeing the injury a surgeon should be able to define, exactly, the heat to which the temperature in any particular case is likely to rise. But no such rule can be laid down, because high fever often follows slight injury; large injuries shew frequently no rise of temperature. With the discovery in these so-called septic matters of minute living organisms, which are now generally recognized as the causation elements in the infective fevers, new light has been shed upon a previously obscure subject, and the study of fever has received fresh impetus.

There is therefore no special pyrogenic substance, as the exciting causes of fever are many. In the acute infections, as for example scarlet fever, small-pox, and cerebro-spinal meningitis, the febrile temperature is caused either by the direct action of micro-organisms upon the nerve centres, or by the action of a poison which bacteria develop within the body.

In many other febrile states, as in those resulting on injury, the elevation of temperature may be due either directly to the entrance of minute organisms, or to their impression on the nervous system. BILLROTH thought that fever in a wounded person was proof of decomposition having occurred in the wound and the passage of these products into the blood; but VOLKMAN believes the symptoms in either case to be sufficiently distinct to be called septic and aseptic fever, according as to its microbic or irritative origin.

ROSENLEACH discovered, in different fetid secretions, three forms of bacilli (*B. Saprogenes* 1, 2 & 3) which are rather large microbic organisms multiplying by end-spores and when cultivated in nutrient agar-agar, grow in the form of an irregular sinuous streak, with a mucilaginous appearance. They also grow readily in blood serum; but all cultures emit the odor of decomposing kitchen refuse, and when albumen or meat is acted upon by these cultures, it undergoes rapid putrefaction, provided it is exposed to atmospheric air, but if the air is excluded, the action of the microbes is very slight, and a culture becomes harmless when injected into healthy tissues and joints.

The *proteus vulgaris*, recently described by HANSEN, being intimately related to the processes of putrefaction, is capable of altering its form during development, and according to its various forms of growth, the different species of *proteus* is described as coccoid, bacteroid, spindle-shaped, and spirillinear. Many of the rods are

actively mobile, and rapidly liquefy nutrient gelatine, converting it into a turbid greyish-white fluid. Within a few hours after inoculation, into a 5 per cent. solution of nutrient gelatine, the most-characteristic movements of the individual bacilli are observed, on the surface of the gelatine, but not if the nutrient medium contains 10 per cent. of gelatin; Spore formation was never observed. Blank results were obtained by the subcutaneous injection of small doses, but larger doses sometimes caused circumscribed abscess at the point of injection. Whereas, intra-venous injection of a large dose produced toxic symptoms in rabbits and guinea-pigs, and that the toxic element is held in solution is known by the fact that these were not modified by using the filtrate from a liquefied culture.

Proteus Zenkeri occur in rods, about four times as long as wide, in twos like bacterium termo, and do not liquefy nutrient gelatine, but form a thick, whitish gray layer with sloping margins. The bacilli are mobile, and the same phenomena are observed on the solid medium as in the other forms; but spirilli and spiralmar forms are seldom seen. Gelatine and blood-serum cultures emit no fetid odor; but meat infusion undergoes rapid putrefaction with usual odor. The pathogenic qualities are the same as those of the other species of *proteus* by means of the soluble substances they produce when they enter dead tissue exposed to air.

The *proteus mirabilis* occurs in rods of various lengths, usually found singly and in zoogloea, but sometimes in tetrads, pairs, chains, or as short rods in twos resembling the *bacterium termo*. They have the same pathogenic properties as the *vulgaris* and in nutrient gelatine form a thick, whitish layer of concentric circles, which, liquefying the medium, show movements similar to those observed in the *proteus vulgaris*.

LISTER's great life work of antiseptic surgery is based upon the theory that inflammation, suppuration, and septic infection of wounds are caused by living specific micro-organisms. SELINI isolated ptomaines as volatile alkaloids in an exhumed body in 1872. GANTNER made quite similar observations, but believed that the toxic substances resembled the narcotics, morphine and atropine, in their action, and were more nearly allied to the alkaloids of poisonous mushrooms.

Pus and other matters from inflamed parts, when injected into the veins cause pyrexia, which is also produced by septic matters, or by injecting large quantities of water into the veins of animals. Therefore, it is no easy matter to isolate any one material as being the thermogenetic body, and even up to date. "No substance has been isolated, from inflammatory matters, that can by itself produce the pyrogenic effect: as in all the above cases death and decomposition occur in the cells either of the blood or of the tissues, so that the pyrogenic substance, acting like a ferment, breaks up the proteid matters of the tissues and causes increased oxidation."

The term *sapremia* or *sapremic septicemia*, a term introduced by the late Dr. MATTHEW DUNCAN, is the typical form of septic intoxication, always caused by the introduction into the blood of preformed ptomaines or toxins, elaborated from dead tissues by putrefactive bacteria, and is closely related to fermentation fever, as the chemical

phosphates, instead of being eliminated after the removal of the primary cause, immediately, cease and disappear.

Now an sepsis does not occur in the absence of putrefaction of urinary tissue, and putrefaction never takes place without infection with putrefactive bacteria, it becomes necessary to briefly consider the micro-organisms that cause clinical putrefaction.

In the latter part of the seventeenth century KOKKUS and LAMBERTUS claimed that putrid substances contained minute microscopical worms, which caused the putrefaction. By pointing out the resemblance between the symptoms of poisoning by mousages and by atropine, KEINER (1820) raised the suspicion that toxic alkaloids were formed through the decomposition of albumen. PAMUX (1856) showed that the inflammatory change occurring in the intestinal mucous membrane of animals fed on putrid infusions was due to a chemical poison, which remained unaffected by boiling for a long time; and this conclusion was confirmed by WEDER, HEMMER, SCHWENIGER, STICH, and THIERACH, while SIR W. B. RICHARDSON (1875) isolated a toxic substance "septon" (septon) from the inflammatory transudation in the peritoneal cavity.

Urethral fever, which is most often met in the case of old men, catheterised for the first time, begins with rigors followed by high fever, and usually ends in a few days with profuse perspiration. Sometimes, however, it may end fatally as a complication of some chronic renal lesion. The late SIR ANDREW CLARK, who was the first to call attention to the possibility of death taking place, subsequent to the passage of an instrument in old men, without any kidney or bladder trouble to account for it.

He attached great importance to the following points:—

1. In operations for the relief or cure of chronic retention of urine the bladder should not be emptied at once, but a few ounces (at a time) withdrawn and half their volume of some mild antiseptic solution immediately thrown into the bladder, each time lessening the quantity of antiseptic thrown in and increasing the quantity of urine withdrawn, thus removing the tendency to shock, hemorrhage and "urine fever."

2. Tight strictures of the membranous urethra are most safely dealt with by perineal section, but when associated with a pendulous urethra, both internal and external urethrotomy are necessary.

3. Thorough asepsis; as the decomposition of blood urine, or other organic matter, may give rise to urethral fever by producing ptomaines.

4. Those of a highly nervous temperament are the persons most predisposed to urethral fever.

5. All practicable antiseptic precautions should be closely observed in every case of dilatation, to avoid any ill-effects likely to follow the rapid dilatation of old strictures when not preceded by internal urethrotomy.

6. To ascertain the actual condition of the bladder, ureter, and kidneys, and if extensive disease be present, the greatest skill, gentleness, and patience are necessarily called for in the treatment of strictures. If the renal tract is diseased and if in any case one has to deal with

several strictures of very small diameter, it is necessary, with any simple gradual dilatation, to make internal and external urethrotomy with a silver probe, before the internal and external operation—the latter being done first.

7. *Salivæ excreta* no manifest influence over urethral fever.

8. Boric acid, internally, by its resolvent and antiseptic action, doubtless does exert a favorable influence and often proves a prophylactic, if given some days before operating.

9. With a further view to prophylaxis, both before and after all urethral operations, the canal should be injected with some mild antiseptic, and especially after each act of micturition, subsequent to internal urethrotomy.

10. When urine fever persists, despite all treatment, or, after any urethral operation, seems to jeopardize the patient's life, *perineal* section should certainly be done.

The change occurring in the state of the blood vessels is most important, as there are certain forms of pyrexia to which the fever theories, already given, do not apply, and a large number of cases are recorded where, apart from any local inflammation or specific disease, there was a very high temperature, not of course counting those cases where, without obvious cause, there may be increased production of heat from some unknown disturbance of the thermogenetic apparatus, by either central or reflex stimulation.

In the febrile state the phosphates, excreted in the urine, are at first diminished, but as convalescence sets in, they increase to a point considerably above normal.

In health a deposit of urates often occurs after profuse sweating and violent exercise in cold weather. Pathologically a deposit of urates is found in all febrile conditions in grave organic disease, particularly of the liver, and in dyspepsia.

In most febrile conditions albumen may appear in the urine, but usually only in small quantity, and practically not more than is often met with in health; but if the amount is considerable, it points to the occurrence of Bright's disease as a complication. In febrile conditions the elimination of the chlorides diminishes to so remarkable an extent that ROHMANN concludes that this diminution is due not to a deficiency of chloride taken along with the food, but to a change in the relation of the albumen of the blood to the chloride of sodium in the plasma.

Uro-erythrin is a pinkish-red pigment (the *porphyrin* of BIRD) which often appears in the urine of fever, and of cirrhosis of the liver, and attaching itself to precipitates of urates and uric acid, gives them a brick-dust hue. This deposit may occur in healthy persons, from errors in diet and other trifling causes. *Uro-bilin* is a reddish pigment, first described by JARVIS and found in considerable quantity in the urine of fever, and sometimes in that of jaundice.

It is generally accepted that slight trans and excessive heat-production sometimes result in a high temperature, which, involving a stable condition may involve a temperature of 104°F. or 105°F. for some considerable time, and is attended by flushed and dilated face, and a rapid pulse.

the heat which is actually generated, account for the clinical picture of the patient having fever and being cool or hot. Nothing, however, is absent. Now as this loss of heat seems to different subjects, we divide fever into the clinical stages of hot and cold. In the cold stage, the decrease of heat results in the vasomotor changes, making the skin pale and ex-anguine, but there is simultaneously a greatly increased production of heat, ranging from 1½ to 2½ or 3 times the amount of heat normally generated, and the great and rapid rise of temperature at this stage points to the fact that the decreased loss of heat is not the sole cause of the rise of the temperature.

During the hot stage the dilated cutaneous vessels throw off a great amount of heat but at the same time generate considerably more heat. A scale of parallels of heat production in health and in fever has been framed by some authors, who think that with a rise of 1, 2, 3 and 4°C, there is an increased production of heat of 6, 12, 18, beyond the normal, in cases in which recovery has occurred after a temperature of 106°F. I have recently recorded an instance in a case of hyperpyrexia in bronchopneumonia, where the patient recovered from a temperature of 111° Fahrenheit, but five days later, succumbed to a severe attack of convulsions consequent on the temperature reaching to 106° Fahrenheit. We cannot, however, fix the precise limit of temperature which is compatible with human existence, and though we may consider a temperature of 107° as dangerous, and one of 108° so very dangerous that the patient is sure to die; while 109°F., lasting 24 hours, is incompatible with the continuance of life. Ordinarily, a temperature of 106° or 107°, lasting any time, from 24 to 48 hours is fraught with great peril to life, especially if this occurs as a complication to any serious disease.

If in the hot stage of severe ague the temperature suddenly rises to 106°F. and falls with almost equal rapidity, there is little or no danger; but if the disturbance is due to the action of the heat effects on the surface cells of the brain in a long-lasting fever, the danger is very great indeed; there is slower excretory power from slower excretory activity—as proved by the sluggishness with which potassium iodide passes through the system to the urine.

It may be interesting to make a few remarks regarding *Hebber's Fever*, which commonly accompanies prolonged suppuration, from whatever cause, as when the wound cannot be kept aseptic and efficiently drained. It has been ascribed to the drain of the system by extensive pus formation, but this is not the only cause, as a chronic abscess may attain a very large size, and exist for years unattended by suppuration as long as it remains unopened; nor does hebb's fever occur even after opening if the cavity be well drained and the introduction of the pus can be prevented. It is more probable that hebb's fever is due to a chronic blood-poisoning, by absorption of the products of putrefaction.

Hebber's Fever is characterized by profuse sweating, rapid wasting, nocturnal rises of temperature, and sometimes diarrhoea, deposits of urates in the joints, the patient being thin with flushed cheeks and a rapid pulse, tongue pinkish red and dry at the tip, and the patient weak, and as the appetite

gradually fails, the patient becomes weaker, and weaker, and dies exhausted from diarrhoea, lardaceous disease, etc.

The *post-mortem* increase of temperature is particularly striking from diseases such as tetanus, hydrophobia and cholera is probably due to (1) coagulation of the myosin of muscles during cadaveric rigidity, (2) chemical changes occurring within the body and (3) decreased heat-loss from abrogated dissipation. HENSEN and HALM ascertained that before the body of a dead dog cooled, there was a constant but evanescent rise above the normal temperature, and similar facts have been noted occasionally in the human body, immediately after death from muscular spasms or yellow fever. WAXENLICH, who measured the temperature in a case of tetanus some 57 minutes after death, found it to be 45.375°C. or about 122°F., which was due chiefly to the chemical heat generated during the change of the semi-solid myosin of the muscles into a solid form (rigor-mortis). Therefore all conditions causing rapid and intense coagulation of the muscles (e.g. spasms) favor a *post-mortem* rise of temperature; and similar results obtain from a rapid and intense coagulation of the blood. VALENTIN so placed a dead rabbit, in a chamber, that no heat could be given off from the body, and found that the internal temperature of the animal's body was increased, and that the processes which cause a rise of *post-mortem* temperature are more active during the first than the second hour, while the higher the temperature at the moment of death the greater the heat evolved after death.

VOGEL found a maximum quantity of 1275 grains of urea in excessive fever, while the late Dr. PANKA found 885 grains of urea in a case of enteric fever, and noted that the uric acid was almost twice the amount discharged in health. This indicates considerable tissue waste, and, placed side by side with the small amount of food consumed by the fever patient, accounts for the defective nutritive condition of almost every organ of the body towards the end of a prolonged fever.

Professor BURDON SANDERSON directly opposed this view, and, while admitting that as the heat-production of an individual on fever diet and that of a fevered person is excessive, says it is not by any means greater than the heat-production of health. Dr. ORD makes the following inquiry:—Is it possible that the increased heat of fever may be brought about by the cessation of processes in which heat ought to be used up, either as reaction or chemical action, or other kind of energy?..... Is the increment of heat of body in fever due not only to combustion to or other disintegration process taking place, but also to the persistence, in the form of heat or energy, which should have taken another form? This, he says, appears to me in a high degree probable. Throughout the body we recognise two processes ever going on; the building up of tissues on the one hand, the disintegration of tissues on the other. The disintegration of tissues is clearly attended by the liberation of heat. Their building-up presents itself to me as necessarily attended by the consumption or dissipation of heat, which assumes some other form of energy, kinetic or potential. There is no direct (experimental) evidence, but we may gain some help from a consideration of the chemical processes in fever. These

comprehend, in the first place, the exaggeration of the combustion of health. But they also comprehend changes which exactly reverse those of health, and indicate strongly that there is, first, a cessation of the changes which occur in health; and secondly, a production of changes not occurring in health. The proportions of soda and potash which should be eliminated from the body in health are reversed in fever. The same holds good of chlorides, and phosphates which are the associates of highly organised principles. Again the chlorides and the soda salts are due to the introduction of further organized principles. On the view that there is in fever arrest or default of the building up of the tissues, one can imagine the retained chlorides and soda waiting with the organic substances, till at the end of a fever they part with their associate organic matters, and pass on to the elevating influence of the potash and phosphates. We can imagine the potash and phosphates during fever swept away as useless, because in the arrested ascending metabolism they have nothing wherewith to continue, and are, for the time useless, fit only for the draught. It is, in fact, presented to me strongly that these chemical variations indicate the cessation, in various degrees, of that process of tissue building which should in health use up heat, and which, ceasing in fever, leaves heat to run wild." He next details some ingenious experiments as to the temperature of growing cucumbers and bananas which so far as they go, seem to support this view, and finally states; "I believe that in the production of fever heat there is a first factor of increased oxidation or combustion, or disintegration setting free heat. I cannot, however, find this sufficient to account for all the increase of fever observed in pyrexia. The further increment I believe to be furnished by heat going astray in default of correlative change in metabolism. And, like DR. PROOBLIENT, I am inclined to recognise in the nervous system the power, inciting on the one hand disintegration, controlling on the other the nutritive functions.

What I would suggest is, that in all fever, slight or intense, there is superadded, to the combustion which we recognise, an influence of nervous system—a trophic influence—arresting processes, in which heat should be transformed; and that the increasing temperature of fever is determined by increase of this inhibitory influence.

From experiments on various animals as to the effect of hunger on their susceptibility to infectious disease, CANALIS and MORFENGO conclude:—1. Animals naturally immune to infectious disease can be made susceptible by hunger.

2. Pigeons, usually immune, always die of anthrax when starving is commenced at the time of inoculation.

3. Pigeons, which have been starved during six days before inoculation, do not take anthrax if feeding is commenced immediately after inoculation. If the starvation lasted more than six days, they, as a rule, take the disease.

4. The readministration of food retards the course but not the development of anthrax if the pigeons are allowed to feed during two days after inoculation.

5. Total or partial extirpation of the pancreas renders the pigeon susceptible to anthrax during a limited time.

6. Anthrax will finally develop in inoculated pigeons, even if starving is not commenced until eight days after ward.

7. The bacilli of anthrax introduced under the skin of immune pigeons remain alive and virulent for several days.

8. The loss of immunity in pigeons depends not on the depression of temperature during starvation, since the disease is not taken, if a similar depression be produced in other ways, and the animals be abundantly fed in the meanwhile.

9. Chickens also may be made susceptible to anthrax through hunger.

10. The majority of the animals of this species died of anthrax, if starved for three to seven days before inoculation and after it also until dead. They do not, however, take the disease if starvation is commenced only at the time of inoculation.

11. Adult white rats experimented on remained entirely immune from anthrax, even when allowed to starve for a comparatively long time before inoculation.

—:O:—

PERSONAL HEALTH.

BEING A LECTURE BY S. J. MULLEN, C.M.S.,

Srinilliputr.

PERSONAL HEALTH or personal hygiene is the science of individual health. As there are public acts and laws promoting the health of communities, so are there rules and habits of life, by attention to which the health of the individual may be preserved or increased and a knowledge of these is absolutely necessary to understand how the rules and regulations of public health improve the condition of the people at large. Health is a bodily condition easily comprehended but difficult to define. It is dealt out in different measures at different periods of life, and is perhaps best defined as exemption from disease or that state of body necessary to perform every function which can be reasonably required of it, and to accomplish each ordinary task, whether of brain or muscle, without pain or sense of fatigue."

The following are the signs of health:—(a) Good constitution; (b) adaptability to widely diverse conditions of life or of climate without deterioration of energy (c) endurance; (d) self-control, mental, emotional, and sexual and (e) resistance to morbid influences. From birth onwards to old age, health varies with the body and, according to wear and tear at different epochs of life, the strain is felt in different parts, falls upon different organs, and tissues in proclivity to disorder of their several functions, whether in wear or in degeneration of the tissues of which they are built.

Value of Health. Health is one of the greatest earthly blessings, the full possession of which makes mere existence enjoyable; our work no burden, our sleep at night sound and refreshing, and time glides along pleasantly. How different in the case of sickness! With our inability to discharge our own duties, and ourselves a source

of trouble and anxiety to others. Without health rich men, amidst their possessions, nobles yea, even kings and queens are miserable, while the healthy though poor labourer, earning his bread by the sweat of his brow, finds life really happy. We are affected by the sickness of others, as well as by our own. If a child is seriously ill, all in the family feel anxious, and considerable expense is also involved. It is still worse when a wife or a good mother, who is busy from morning to night providing for the wants of her husband and children, is confined to bed by severe illness, and herself needs to have everything done for her. What a misfortune when the father of a family gets sick and loses his wages, yet has to pay for medicine and a doctor. Lakhs of rupees are thus daily lost in India and many a man gets into debt while his family may be thrown into great distress for a long time. The father may even die, his wife becoming a widow and his children orphans. Even should a man survive, a sharp attack of fever often saps his strength, making him infirm for life and rendering him predisposed to other diseases which may prove fatal. As disease is no respecter of persons, and may also become hereditary, the immense value of health is more than apparent.

Supposed causes of Sickness.—In many parts of the world, sickness is attributed to demons or to witchcraft, and some people are so ignorant that rather than give medicine they trust entirely to devil-dances and charms. In India, cholera and small-pox are especially ascribed to demons or goddesses. In the north a new goddess called ALA HIBI is thought to preside over cholera. The small-pox goddess is worshipped under different names: (*Satala Devi* or she who cools, *Mari Amman* or mother of death) in every part of India, where she is supposed to scatter the seeds of the disease for her amusement, and when a person in Southern India is stricken by small-pox, the people say "The Amman is taking her pastime over him." Many of them refuse to vaccinate their children for fear of displeasing the goddess by interfering with her sport. A common Hindu tradition lays all diseases as the fruits of sins in a former birth and considering it impossible to escape the results of *Kurma* declares that what is written by Brahma on our heads must inevitably happen. It is true, however, that many children fall victims to dreadful diseases handed down by their parents and ancestors. A Persian proverb truly says:—"The proper devil of mankind is man;" as it is from the ignorance and misconduct of ourselves, our fellowmen or our forefathers, that we chiefly suffer.

True Causes of Sickness. The world, around us, contains a countless number of different articles, each of which has its own properties—fire will burn, arsenic will kill, bread will nourish, and the only safe course is to gain a knowledge of the properties of bodies and use them accordingly. Substances, wholesome in themselves, become dangerous when mixed with poisons. Put some arsenic in a vessel of pure milk and the whole must be deadly. (a) The influence of water on health is acknowledged by many people in India. And nearly half the sickness in this country is caused by impure water. The greater part of our bodies consists of water. The water we

drink passes into the blood and thus goes to every part of the body; if the water is bad, the health must suffer. (b) Air is an important element; most needed to sustain life. We can survive several days without food, but the strongest man will die in a few minutes without air; we not only need air but the air must be pure. "Fresh air is the breath of life." (c) Improper food is another frequent cause of disease. Certain articles are liable to cause diarrhoea, which, when the disease is epidemic, may run into cholera. The proverb "taken in excess even nectar is poison" applies to food. (d) "Fifth is the mother of sickness," and in some form or other she is the *Mari Amman* or mother of disease.

Health is largely secured by (1) good water, (2) pure air, (3) suitable food, and clothing and exercise, and (4) cleanliness. Two hundred years ago, the average duration of life in England was only about 20 years; it is now 41 years, and this extension has been brought about by sanitary reform. At present the annual mortality for all India is not less than 34 per thousand or 6,800,000 a year, involving 136,000,000 cases of disease. If it could be reduced to the English standard, the mortality would sink to 4,400,000, and the cases of sickness to 38,000,000, making an annual saving of 2,400,000 persons from death and 48,000,000 from sickness. The diffusion of the knowledge of the laws of health lies at the root of sanitary improvement, and though sanitation is now, one of the subjects taught in many schools still, is very desirable that the principles should be understood by the leaders of native society, some of whom hold Government appointments, others are Municipal Councillors, and all of these more or less exert a direct influence on the mass of people. These should first clearly understand that *disease in the animal kingdom is regulated by the same laws as in the vegetable world*. As diseases do not arise of themselves but each has a separate cause, and every infectious disease has its own seed, which reproduces it just like the different kinds of grain, while the very processions and ceremonies on which the people rely for deliverance from epidemics really increase the evil. It is our duty to first gain a knowledge for ourselves of the laws on which health depends, and then to set an example in carrying them out by making our children and servants observe these closely; and lastly we should do all in our power to make them known and acted upon by all others, over whom we have influence. By following the rules of health lakhs of lives would be saved in India every year, and an indescribable amount of suffering and misery prevented. Miss NIGHTINGALE says: "Since the world began, criminals have not apparently destroyed more life and property than do epidemics every year in India." There are general rules for the preservation of health, but to guard against particular diseases special precautions should be taken.

(To be continued.)

A MIRROR OF PRACTICE.

A CASE OF PARAMETRITIS: RECOVERY.

By DR. PATE RAM BANADUR, C.M.S.

Simla.

Mrs. L., aged 19, had been delivered of a full-term child on the 2nd October 1894. It was a natural confinement, but there had been hæmorrhage after delivery, and the midwife in attendance had administered a dose of ergot. On the evening of the 4th instant she had a slight rigor, the temperature rising to 103°F.

On the morning of the 5th I was sent for, and found the temperature 103°F, pulse irregular, the patient pale and anæmic. I was not allowed to make a vaginal examination, but on enquiry, was told that the discharge was scanty; that evening the temperature rose to 104°F, and the discharge stopped entirely. A dose of salicylate of soda was given, and the midwife was told to syringe the uterus with Condy's fluid.

On the 6th the patient complained of pain in the hypogastric region. Bran fomentations were applied over the painful parts.

7th.—Temperature 6 A.M., 103.4°F, slightly delirious, complained of the pain being very severe; discharge scanty and offensive. My order as regards syringing the uterus had never been carried out.

8th.—Temperature 104°F at 9 A.M.; discharge very offensive; abdomen slightly distended. Surgeon-Major MOORHEAD was called in in consultation, and decided that the case was one of Parametritis, phenacetin 8 grains given every four hours, if necessary; a pill containing 2 grains Pil Hydrarg and 1 grain extract opii every 6th hour, and quinine; temperature fell to 100°F, mustard and linseed-meal poultice over the affected parts.

On the 9th the temperature rose to 106°F; the patient seemed in a critical state. Dr. MOORHEAD administered a tabloid of morphine and atropia sulph., and ordered the following mixture:—

| | | | |
|-------------------|-----|-----|---------|
| R Pilocarpine Nit | ... | ... | grs. i. |
| Liqr. ammon acet | ... | ... | ʒi. |
| Spt. ammon arom | ... | ... | ʒiii. |
| Spt. chloroform | ... | ... | ʒiss. |
| Aq. camph. | ... | ... | ʒvi. |

On the 10th and 11th the patient continued much the same; the temperature rising to 105°F; the discharge was less offensive, and the pain not so severe.

On the 12th a distinct hard swelling, about the size of an egg, was detected in the region of the lateral ligament, which was painful on pressure. Vaginal douche continued and plugs soaked in carbolic acid and glycerine, inserted three times daily.

On the 13th the patient seemed better. Her temperature rising only to 101; discharge free and healthy. On the 14th, 15th and 16th she made steady progress. On the 17th the swelling had disappeared. Treatment was discontinued with the exception of the vaginal douche.

She was ordered Fehle's syrup of hypophosphite of lime and extract of coca.

From this date she gradually recovered and on the 7th of November left Simla for Calcutta.

SPORADIC CASE OF ORBICULAR MENINGITIS: RECOVERY. BY ITS DISSEMINATION. BY AN INJECTION.

By JAMES E. WALLICE, M.D., L.M.S. (LOND.)

L.M.S. (London).

Calcutta.

G. K., a European planter of 25 years of age, was brought to me in July last in great distress, suffering from agonising recurrent pains about the middle of the sternum. He had been having these spasms about every five minutes for nearly three hours. They came on while he was eating his breakfast. He had taken a dose or two of chlorodyne, applied hot fomentations and a mustard plaster to his chest to relieve the pain, but to no purpose. He was pale and exhausted. Each effort to speak or to swallow his saliva brought back the pains. I inquired carefully into his case to ascertain the cause of the spasms, but could get no light on the subject. He had just returned home from Assam and was very hungry. He had had fever for some days and had eaten hardly any food during the time. He felt famished, but fearing to partake of anything difficult of digestion, he tried to eat a half-boiled egg mixed with some boiled rice. He had scarcely swallowed the second spoonful when the acute cutting pain in his chest began. He drank some tea but the pain got worse. He used the remedies already stated, and finding no relief, he hurried off from Ballygunge with his sister, to my consulting rooms.

I examined his chest stethoscopically; but no time was afforded to the nature of his trouble. I gave him a dose of morphine and made him sniff small doses of chloroform. The pains instantly ceased, but, as the effect of the anæsthetic wore off, back they came. I concluded that something had stuck in his gullet, though having eaten nothing but two spoonfuls of mashed egg and rice, I could not conjecture what the foreign substance could be. I decided on giving him an ipecac emetic, and so he was asked to take 40 grains of the powdered drug in water and this was followed by copious libations of tepid water. Scarcely had he got down about two pints, when he vomited freely and up came the top of an egg-shell, certainly the size of one-third of the whole ovum. The pains ceased absolutely and at once, and returned no more. The patient and his awe-stricken sister both laughed heartily and I felt like joining in the chorus myself, for it seemed almost incredible that a person could bolt down a third of an eggshell and be unconscious of the fact. Yet I record a fact, and my patient, who is a well-known planter, will smile when he sees this authentic account of his strange and unaccountably caused woes.

A SPORADIC CASE OF ORBICULAR MENINGITIS: RECOVERY.

By SUREN CHAT. PATRAK HANNA, M.D., M.B., B.S., L.M.S.

Lecturer on Pathology and Clinical Medicine.

Hyderabad Medical School.

CHANDAN BABA, aged 21 years, was brought to me on the 23rd August 1897. He had been suffering from fever for several days, and on the 22nd he was followed by vomiting, the temperature rising to 104°F.

...and severe headache, vomiting, and great pain and spasm of the muscles of the neck and abdomen; the head was drawn back, and the patient was in a state of rigidity. On the 18th convulsions of the body took place which with short intervals lasted for 36 hours. There was rigidity and contraction of the muscles of the neck, so that the head was forced backwards, the neck forming an arch (there was great difficulty in treating the respirations being occasionally spasmodic) the muscles of the spine and abdomen were also contracted, causing the case to resemble one of tetanus. There were no complications.

He now began to suffer from excruciating pain in the occiput and back of the neck, with shooting pains down the arms, as far as the middle of the forearms. There was great difficulty in swallowing. On the 5th September the fever went down to 99. We now gave 24 grains of quinine in two doses. The spasms ceased on the 9th, and there was no return of the fever.

There was a distinct history of poverty verging on chronic starvation, as well as repeated attacks of ague. There was also a slight enlargement of the spleen. The disease was not tetanus. There was rigidity of the neck and upper part of back, but not of the extremities, nor were there the spasmodic convulsions and lockjaw which occur in tetanus. There was no difficulty in micturition or defecation; the eyes were calm and not fixed, and although congested, had not the peculiar appearance they have in tetanus, early in the disease; the first sound of the heart was distinct, but later on it became muffled, and difficult to follow on account of the rapidity of the heart's action.

Treatment.—Blisters were applied behind the ears and cold water to the head and back of the neck for six days.

Hypodermic injection of $\frac{1}{4}$ grain of morphine to induce sleep, but later on the dose was increased to $\frac{1}{2}$ grain, and a dose of bromidia given every six hours.

In convalescence quinine and iodide of potassium, iron and cod liver oil were given. Diet was simple, consisting of milk, soup and farinaceous articles; no alcoholic stimulants were used.

TWO CASES OF SERIOUS PENETRATING WOUNDS OF THE CHEST AND NECK: RECOVERY.

By CHOITHRAM, SHEWAKRAM, C.M.S.

Adami, Hyderabad.

Case No. 1.—Ramzan, aged 25 years, was brought to the dispensary on the 14th February 1895. There was a deep wound, on the chest between the right nipple and sternum, which the man said was caused by the entrance of a thorn. Afterwards I learnt that, about a fortnight previous, he had been stabbed with a pair of scissors by his cousin.

On examining the wound I found it to be about 3 inches deep, with a very offensive discharge; the patient was weak and swallowing and breathing seemed difficult; pulse weak. The wound was irrigated and dressed.

On the 14th, a quantity of offensive pus came away, a drainage tube was inserted, and the wound dressed as be-

fore. On the 23rd, the tube was removed and the wound dressed with carbolic oil. There was no discharge, but improved steadily and was discharged on the 26th.

Case No. 2.—On the afternoon of the 20th March 1895, I was called to see a native lad of about 10 years, who had received a wound which penetrated through the neck, from right to left.

The father of the lad stated that his son had had a fall from an ass, and that a pointed piece of stick which he had in his hand had entered his neck, passing right through it. The stick was forcibly extracted by the father, upon which excessive hemorrhage took place.

The boy was conscious, but could not speak or swallow properly. I did not probe the wound, which was clean, both at its entrance and exit, but dressed it antiseptically.

The next day he had a little fever, there was a slight discharge, and the wound looked unhealthy; but from the 24th the boy improved daily, and on the 2nd of April he was discharged cured.

A CURIOUS CASE OF HYSTERIA: RECOVERY.

By KALLIPATTI C. SUBRAMANIAN, PILLAI, C.M.S.

Amrath, Kanyur.

BAHIRATTI Amman, Hindu female aged 27 years, came to my dispensary suffering from nervousness and hysterical symptoms. She stated that two years previously, she had had a severe mental shock.

She was very nervous and agitated, and shuddered repeatedly whilst recounting her symptoms. She stated that she was subject to fainting fits and palpitations, and had a dread of ultimately becoming insane.

Her organic functions were slightly disordered, loss of appetite, a slight nervous cough, kidneys irregular in their action, and the skin cold and moist.

For the first 12 days the treatment consisted of an aloetic purgative every alternate day and an ordinary saline mixture containing potassium chlorate three times daily. She improved rapidly under this treatment. On the 14th day she complained of nausea and an inability to retain any food. Sulphur magnesia with 10 drops of sulphuric acid was given, and had the effect of checking the nausea completely. On the 20th day she left the hospital stating that she felt quite well and had not experienced any nervous symptoms for the last five days.

INOCULATION OF TUBERCULOSIS THROUGH TATTOOING.

COLLINGS has reported three cases in which local tuberculosis developed as the result of tattooing by a tuberculous person, who used Indian-ink rubbed up with saliva in the palm of his hand. The tuberculosis was conveyed by a lad, fifteen years old, who subsequently died of advanced pulmonary tuberculosis. A short time before his death he tattooed two of his brothers, aged thirteen and ten years, respectively, and a friend, aged fifteen years. The arms at the site of inoculation presented pustules and ulcers. In all three cases there was enlargement of the epitaxial and axillary glands. The general health of the boys did not suffer appreciably. The lesions were all seen by Mr. JONATHAN HUTCHINGS, who expressed the opinion that they were due to the inoculation of tubercle. A piece of skin from the arm of one was examined and presented well-marked giant-cells in the corium, but tubercle bacilli could not be demonstrated. —M. M. J.

THE Indian Medical Record.

16th October, 1895.

SOCIAL OFFICIALISM IN THE INDIAN MEDICAL SERVICE.

"INDIAN sanitation is not a scientific but an official system." It was thought by many, who read Mr. ERNEST HART's epigrammatic strictures on the Indian Medical Service, that his implications in the above epigram were not in accordance with the actual state of things in that service. A more serious and damaging accusation could not be brought against any medical service than to characterise it as dominated by the "official" instead of the scientific spirit. Medical science, if not scientific in the nineteenth century, is quackery of the very worst kind. But it is not so much to the individual members that Mr. ERNEST HART's strictures apply as to the system by which promotions and appointments are made in the higher branches of the service, whereby true merit is overlooked and scientific attainments and original research are discountenanced and discouraged. If the official element of the Indian Medical Service, connected with and controlled and regulated by a great Government, is permitted to dominate the scientific element and overrule it—giving science the lower, and social officialism the higher positions,—then the charges brought against their service by Mr. HART are well founded and well deserved. Whatever abuses have existed in the past, or do exist at the present time in the Indian Medical Service, were and are due largely to the element of what we may call—for want of a better name—*social officialism*. This *social officialism* is found throughout the various provinces of India, and has its head-quarters, as is met, at the fountain-heads of Provincial Governments, such as Calcutta and Simla. This dominating principle calmly overlooks and deliberately discourages scientific and literary merit, which has always existed in the service. A most glaringly pronounced instance of this kind of official outrage has recently been perpetrated by the appointment of Surgeon-Captain DYSON to the Sanitary Commissionership of the Government of Bengal: overlooking the scientific merits, official experience and literary attainments of Surgeon-Major LAWRENCE WADDELL, the Deputy Sanitary Commissioner. How this has come about, we do not wish to enquire, as it would lead us to expose a system of social favoritism in the Bengal services which we had feign hoped, had come to an end with the advent of SIR CHARLES ELLIOTT to the Lieutenant-Governorship of Bengal. Doubtless the nomination of a successor to Dr. GAMCO lay with the Government of Bengal, but the final power of appointment is, we understand, invested in the Government of India, who no doubt acted on the nomination made by SIR CHARLES ELLIOTT. The Lieutenant-Governor must therefore take to himself the credit or odium of such an appointment, whether the name of the nominee was suggested to him by his secretaries or not. Here is a young man with no reputation of possessing, as far as we know, scientific, literary, or administrative abilities for such an

appointment, made to step over the head of one of the ablest scientists in the Indian Medical Service. DR. WADDELL has left his indelible mark upon every appointment which he has held in Bengal. As professor of Chemistry and Pathology he investigated and placed on a sound scientific basis the true nature of *abrus poisoning*; his researches on snake venom and the nature of the auto-immunity possessed by venomous snakes anticipated Professor FRASER's alleged discovery of antivenom. He has made a special study of bacteriology under KOCH. His thorough knowledge of the vernacular language, together with ten years' experience of the duties and responsibilities of the Deputy Sanitary Commissionership of Bengal, all pointed to him as the most competent scientific sanitary expert, as well as the most distinguished medical officer in the Bengal service, thoroughly fitted to fill completely the high office of Sanitary Commissioner of Bengal. The only reward obtained officially by DR. WADDELL for his original research and valuable contributions to science is to have the chagrin of seeing a younger and less competent man,—whatever his latent abilities may be—who has as yet made no reputation, or shewn any particular aptitude for scientific research, placed over him officially. We say *officially* for DR. WADDELL's reputation as a scientific investigator of European fame cannot be lowered by any piece of official outrage of this kind. The calm, clear decisions of the tribunal of science will uphold, as we believe, his future contributions to science will extend, his scientific reputation, whether it is adequately recognised officially or not. The knowledge that *transactions* of this kind—for they cannot be called scientific appointments—are not uncommon in the Indian Medical Service, has sullied the fair name of the service, and given occasion for the just strictures made, and the shafts of ridicule levelled at the system by Mr. ERNEST HART and others. But the Government of India or the Government of Bengal should not allow this matter to pass without an equivalent appointment being provided for DR. WADDELL. His enthusiasm for original research, his biological studies, his thorough knowledge of physiology and physiological chemistry, point him out as a medical officer peculiarly fitted to occupy the first rank in sanitary science and scientific research in India. This overlooking of the claims of a medical officer of such acknowledged scientific attainments will do much to discourage original research and scientific enthusiasm among the younger members of the service; and that at a time when those qualifications are most needed and most urgently called for. It was hoped by those who had the best interests of the service at heart,—and who deplored the too well founded reproach of no original research being done by its members,—that the just recognition of the merits of such men as DR. WADDELL would usher in a new era of scientific progress, and roll away the standing reproach of the Indian Medical Service.

INDIAN CHEMISTS AND DRUGGISTS: A SERIOUS PUBLIC DANGER.

DRIVING or walking round Calcutta, or any large town in India, we see numbers of houses fronts ornamented with the very significant "CHEMISTS AND DRUGGISTS" where we

our shop is to find a huge array of bottles, gallipots and pill or syringe boxes, containing patent or proprietary medicines, guaranteed to cure every mortal ailment under the sun, while in some remote, or obscure, corner of the establishment—of course we do not mean the very few large firms—we notice a scrummy table backed by dust-laden shelves carrying, for dispensing purposes, a few bottles containing for the most part expended tinctures that might almost be considered more ancient than the debris of the great deluge.

We have always striven fairly, squarely, and might and main for the elevation of *everything* connected with God's noblest gift, the medical sciences, and though we do not belong to the Mother Grundy category or the class of pessimistic creatures that see nothing good or bright in life, we cannot but insist that these sign-boards are deliberate misnomers and frauds, for though a chemist may also be a druggist, still a druggist is not a chemist; and it would be a keen insult to think that 99.5 per cent. of the keepers of these establishments were actually guilty of the crime of knowing anything about chemistry.

True that without chemistry pharmacy could not exist, and in some cases *vice versa* but a part is not the whole and pharmacy (*dhari or dawa-sazi*) constitutes but a very little part of chemistry (as defined by the Hindustani *Kimiyagari*), and in very truth the average Indian pharmacist is merely a compounder or dispenser; or, in other words, a person who, on the strength of a doctor's prescription or some proprietary remedy, compounds or mixes together crude drugs or prepared chemicals, without the slightest knowledge of the reactions, or actual chemical changes and combinations consequent on such mixing or placing together, and in 99.99 out of every 100 instances having no idea whatever of the therapeutics or pharmacology of the mixture, bolus, powder or wash, he has made up.

To him the laws of natural philosophy or physics are marvellous yet unapproachable mysteries, the atomic theory and its applications would drive him crazy, the very thought of analysis or synthesis would frighten the life out of him, and the sight of a prescription written in chemico-symbolic parlance would prompt immediate suicide. He knows (at least he declares he does) what alcohol is but C, H, O would be an insoluble riddle; and he could no more tell the difference between an *-ate*, *-ite*, or *-ide* or an *-en*, *-in*, *-ine*, or *-one* than he could soar in the skies without a balloon or wings.

Chemistry, Pharmacy and *Materia Medica* depending on each other for material and mutual support are yet separate and distinct sciences, all of which form essential portions of every medical man's curriculum, and though *materia medica* must constantly be kept in mind during the whole of the physician's after college career still only 4.001 per cent. of the doctors are chemists, and about 6.05 per cent. are pharmacists.

In every civilized country under the sun, save India, a place of business where prescriptions are filled or drugs are retailed is called, a dispensary, pharmacy or a drug store, and the persons in charge are known as apothecaries, compounders, dispensers, drug-clerks or pharmacists (but not chemists) and stringent laws prohibit them from prescribing or in any otherwise usurping the doctor's

powers; but India is a land of anomalies where by some peculiar series of illogical reasoning and evolution the germ, who has passed an exceedingly easy compounder's examination, takes his chair at the receipt of custom behind a huge sign-board "Chemists and Druggists," argues himself into a pharmacist, because he is a certificated compounder and so on, by progressive stages, until he convinces himself (hang, what the world thinks) that he is a chemist, and feels confident that he is competent to treat disease, "for is he not a chemist and does not chemistry form an essential portion of the doctor's training?" Henceforth he is "Doctor Babu," and in trying to extol himself he defames the entire faculty of medicine as well as does more actual damage to humanity than it is ever possible to conceive or repair.

Taken in their widest applications and their strictest meanings, it is simply impossible to confuse the terms pharmacy, *materia medica* and chemistry with each other, or to submit a plausible reason to justify the sign "chemists and druggists" over the door of a drug store.

Pharmacy teaches how medicines are prepared or mixed together and their doses; but *nothing* else. *Materia Medica* has several sub-divisions and tells the sources, physiological actions, and medicinal properties of drugs on various conditions of life and health, and there it stops. *Chemistry* is the science that shows the nature and properties of all bodies, medicinal or not. It reduces to their elements the thousands of various compound bodies resulting from the action upon each other of the simple substances of which the universe is composed. It enables us to fathom some of nature's secrets, detect frauds and crimes, and explain hundreds of phenomena that pharmacy or *materia* cannot give the slightest conception of: Therefore the pharmacist or compounder is *not* a chemist, who is a man of a very superior education.

When in our previous issues we contended for a higher standard of education and a stiff examination for compounders we declined against the injustice of placing these men on the same footing as those possessing the certificates of the Pharmaceutical Society of Great Britain, with its severe tests, and shewed how utterly inadequate the requirements of the Bengal Pharmacy Act were to the proper training of a class of men, on the correctness and efficiency of whose work depended not only the lives of the general public but the reputation also of the prescribing physician.

We shewed beyond dispute that, as it stood, the Compounders' Act was practically, and to all intents and purposes, a dead-letter, remarkable rather for its exceptions and neglect than for its observance; and that it is a cruel and sinful farce to place power over life and death in the hands of illiterate men who were totally incapable of holding the solemn trust reposed in them, and few indeed of whom know what incompatibles are, while very many have a happy knack of substituting trashy or expended drugs in place of reliable medicines prescribed: Therefore, to call such men "chemists" is to wilfully insult a large class of educated men (from Western Schools) who have made chemistry a special study to which they have devoted long hours of hard work, unspeakable patience and application, and a mist of money—not two years merely in learning one single book of about 350 pages of fairly large print.

WHAT THE BRITISH SOLDIER THINKS OF THE PRESENT ARMY NURSING SERVICE OF INDIA?

There are some things that indeed "die hard," and the Nursing Department of the British Army in India is an institution which promises to enter into the category of "die hard." From its very inception it was clear to all, but the most prejudiced, that such an institution was not a necessity; or, to put it in the mildest way, it was regarded as an expensive luxury which India could ill afford. We hoped, however, that when those who had given birth to this plan of nursing the British soldier in India, and who nurtured and protected it under their parental wings left the country, that this pet creation of over pathotic minds would die of inanition; but we fear that, if it is dying at all, it is dying but slowly, and that it will die hard. We said a great deal in more than one issue of this journal in depreciation of so lavish an expenditure for which infinitely more substantial and extensive nursing provision can be made for the sick soldier by the utilisation of indigenous labor; and we also pointed out that, even accepting the dictum that "medical friction beyond all contradiction is far better applied by a *she* than a *he*," nursing comrades have served, and will serve, all the needs, in the way of nursing, of the sick of our station hospitals. The kindness, tenderness, and we may almost say affectionate attention which a nursing comrade generally gives to his sick brother-in-arms is but too well known to all with any experience of British hospitals in this country; and it will be most ungenerous of army medical officers not to speak in most commendable and highly appreciative terms of their nursing orderlies. At all events it must be conceded that there is in the British soldier the material for the making of a good nurse; and if those interested in this matter will but divest their minds of all prejudice, and of that sentimentality which seems in none but the feminine touch that tenderness, and in none but the feminine breast that sympathy and kindness so comforting to and necessary for the sick, and if they will but consider the question in all its bearings, they will admit that the nursing requirements of our sick European soldier can best be met by the employment of efficient nursing orderlies. If the system of training a percentage of volunteers from each company be properly conducted, and inducements in the form of extra pay and rations during their employment as nursing orderlies, were offered the men, we may depend upon it that the sick soldiers will never die for the want of efficient nursing. We have said before, and we say again, that one of the most disastrous consequences of the introduction of the nursing branch of the Indian Medical Service has been the withdrawal practically from many serious cases of the professional attention, interference, and supervision of the Warrant Medical Officers, and the substitution of a non-professional meddlingness of the sisters in charge, for the twenty, or more, hours that a medical officer is away from hospital out of every working day.

We have been forcibly reminded of all that we had previously written on this subject, and have been induced to return once again to a consideration of it, by a

letter addressed to me by a gentleman who writes under the name of "SOLDAT." He writes on behalf of the "rank and file" of the army, and should be very glad if the old system of nursing were obtained in all hospitals. We think that just as good results would happen if it did. Neither our modesty, nor that of the lady nurses would then be flattered. Still, the same opinions were rather generally expressed very shortly after this nursing service was introduced into this country; and an extended experience has served to substantiate those views. We have no doubt that if the continuance or abolition of this service were balloted for in the British army of this country, there would be a marked, and probably an overwhelming, majority in favor of abolition; and we cannot see how any practical mind can find in this expensive sisterhood of lady nurses the best and only means of improving the sick man's chances of recovery, and soothing the dying soldier's pillow.

We think that every soldier leaving this country has it in his power to rid the comrades, whom he has left behind, of a nursing system to which he is so positively averse. The time-expired and other soldiers going home should not rest content and satisfied that their connection with any evils or inconveniences attending soldiering in India has come to a close; but they should, by loudly voicing those evils and inconveniences at home, try to relieve their brethren-in-arms, out here, from them. The British press is ever ready and willing to represent and give publicity to any matters affecting the health and comfort of the British soldier, and if all those who go home will, in consideration of the feelings of their comrades abroad, let the British press know their candid and unbiased opinion of the Indian nursing system, they will be discharging a duty which they owe to their military friends in the East. We hope that our soldier correspondent, who writes under the *nomme de plume* SOLDAT will set the ball rolling when he goes home, and that he will be able to get together a good "number to keep the ball in motion" until it reaches the goal, SOLDAT is evidently anxious it should reach, when he says "the lady nurse, out here, is an expensive luxury, which we, as soldiers, would be glad to see abolished." SOLDAT finishes us with a few more opinions, which he gives us to understand are shared by the bulk of the British Army in India, with reference to the Indian Nursing Service. We would enumerate them in quoting from his letter thus—(1) "We rather think that the corps of lady nurses has been raised to assist the daughters of gentlemen" (2) "The army nurses, in our opinion, are raised from the wrong class: as they are, with few exceptions, too big for their boots: and try to ape the doctor. Their sole duty at present appears to be to giving themselves airs, and to ordering the soldiers, orderlies and ward servants about. What their true avocations are, we are at a loss to understand, and think (3) that if they were attached and the money paid to them, expended in raising the pay of the Army Hospital Native Corps, it would be more to the advantage of the service." We think that the lady nurses have taken up nursing as a *dessein* career. In this country their professional

...and they have no... that this is so. The... to Tommy Atkins, but... more generally conceived in... of these India, and however... to their work, this country and the... in it, opposes but a very small and inadequate... for the immense amount of money expended on this... service; and if, in spite of this fact, our Exchequer, notwithstanding the embarrassments, continues to be... color is lent to the supposition that provision... the poor relations of some gentle folk, has been an... object in the establishment and continuance of... expensive addition to the Indian Medical Service. In... of the foregoing opinions we have confirmation... the statement, repeatedly and emphatically made by... us, that the Army Hospital Native Corps can, at a slightly... increased cost, be made to prove highly valuable and... efficient in respect to all the duties that may be required... of it. A better paid Army Hospital Native Corps, and... trained nursing orderlies, will supply all the nursing needs... of our station hospitals; with this advantage that even... in the field or on the line of march, nursing skill will not... be wanting. By failing to hold out better inducements... to the A. H. N. Corps and orderly-nurses, and by... neglecting to improve their nursing efficiency, we are... practically ignoring, or at the best we are making very... scant provision for the nursing requirements of the sick and... wounded on active service.

There is much of a serio-comic vein in the fourth opinion expressed by our correspondent; for although it is a fact that nursing "sometimes opens the way to the hymeneal altar," it is rather funny to conceive the possibility of a guarantee of marriage being given to the fair recruits of the nursing sisterhood. A very fair proportion however of those who entered the Indian Nursing Service have succeeded in forming matrimonial alliances, mostly, we think, with *ex-service* medical officers; and the number of those who have so succeeded, is sufficiently good to raise the hope in the matrimonially disposed "sister," of her soon being able to exchange the worries of sick nursing for the pleasures of her own home. And who can blame her for seeking such an exchange? It is for the good of communities that well ordered and satisfactory matrimonial unions be formed. We do not however mean to suggest that, to effect such good to communities, liberal subsistence allowances be made from Indian revenues to aristocratic needy ones, to induce them to enter upon matrimonial speculations out here; but we simply note how, curiously enough, the great love for her calling, which is an essential qualification of a good nurse, and the great philanthropy which prompts these good sisters to leave home and kindred in order that they may minister to the sufferings of the sick, *vide* in the East—it is we say curious to note, how all these very commendable qualities are put to flight by the gentle dem of Cupid.

We hope that a few more of our gallant sons of Mars will let the Indian and British public know what justice there is in the military expenditure of the country. They have stretched to the utmost involved in the maintenance of the Indian Nursing Service.

COMMENTS AND NEWS.

THE MEDICAL PRACTICE QUESTION IN INDIA.

Our esteemed contemporary, *The Indian Pioneer's Gazette*, continues its series of articles on this subject. Its third article dealing with "HOW MEDICAL ENTERPRISE IS HANDICAPPED," runs as follows:—

"In our previous articles we demonstrated (1) how the medical needs of the civil population in our large cities was efficiently met by the present supply of independent physicians, (2) that there was no need for Government doctors to enter the field of private practice in rivalry with independent physicians, and (3) that Government doctors faithfully performing their State-paid duties are utterly unable to do private work. We would emphasize the two latter contentions by asserting that the Government has already recognised the fact that State-paid doctors ought honestly to do nothing else but their State-paid duties. The Government, we find, has already given practical expression to this belief, by prohibiting certain Hospital medical officers and College professors from engaging in private practice. Thus we find the following officers forbidden to enter this field; the Principal of the Medical College, all the resident officers of the Medical College and General Hospital, the Superintending Surgeon of the Campbell Hospital and the Professors of Physiology, Chemistry, Botany and Pathology. We also find the same principal acting as an interdict on the Health Officer of this city and on the Port Health Officer. No Surgeon in the Indian Medical Service or in the British Service employed on duty with troops in or out of Fort William can engage in private practice, nor is such a privilege allowed to senior officers engaged in administrative work in this city. Now one would suppose that in order to be consistent, this Government prohibition of private practice by certain of its servants, if based upon a sound, reasonable and equitable appreciation of their moral obligation, to devote their whole time to State duties, should logically and legally be applied to one and all of its servants without distinction. Again, if the Professors of Medicine, Physiology, Botany, Pathology, Chemistry and Medical Jurisprudence are considered ineligible to enter into rivalry with private physicians, what peculiar personal advantages are inherent in the Professorships of Anatomy, Surgery, Midwifery or Therapeutics, that a large portion of their time should be devoted, *not* to the advancement of medical science in their special domains, or in the efficient care of their patients in the hospitals, or in the assiduous and methodical teaching of their students, but rather in doing the work of general medical practitioners. We think the public has a perfect right to enquire into the cause of this inconsistency on the part of the Government. For if the public interests are best served in one branch of medical sciences and in one hospital by the officer in charge devoting his whole time to such duties, it is simply logical to expect that the same rule must and should hold good all round. It stands to reason also that if a State-paid officer does not devote his whole time to the fulfilment of his State-paid duties, Government, in closing its eyes to this strange and anomalous fact, is an aider and abettor in a harmful system, and it is high time that these "piums" of the service, which is only a euphonious synonym for roachings, should be swept away.

There is another phase in which this handicapping of private medical enterprises by officials is objectionable and injurious to the best interests of the public. It will be readily admitted that every sculptor or artist necessarily destroys a deal of good material in his earlier attempt to acquire proficiency in his art; so also it may be "officially" charitable

to ignore failures in the earlier experiments of Microtismis, parasitologists and medical operators of sorts, but it cannot be humane or just to the interests and safety of human lives to expect a man to be suddenly transformed from an accountant, a gymnologist, or from a chemist into a high-art surgeon by an announcement in the Government Gazette! Yet this is exactly how the Government in India manufactures its professors. It is often held as an argument by men holding these medical appointments, that they are "picked men of a picked service." Statistics and facts would prove that this assertion is hardly more tenable than the system which permits these men to accept handsome salaries for a great deal of work which they never can do efficiently. There is another phase of serious objectionableness in officer-ing our public hospitals by men of the Indian Medical Service. The incumbents are constantly being shifted from one post to another, and this want of continuity leads to a lack of consolidated experience, and this often leaves the public without any reliable consulting surgeons and physicians. For these men to be relied upon as specialists, their appointments ought to be almost life-term ones. To give point to this contention we will quote some recent experiences in Calcutta. This city had two excellent consulting surgeons, both of whom were men of ripened experience gained by many years of service in the surgical department of the Medical College Hospital. Within a short space of time of each other, owing to the exigencies of the service, both these officers were removed from the sphere of their labors, taking with them a vast fund of surgical knowledge, which in their new posts was of no use to them or anyone else, and by their departure, Calcutta was left almost destitute of consulting surgeons. Strange also that a similar incident supports our contention on this score with regard to consulting physicians in Calcutta. Three able consulting physicians, whose age and mature experience gained for them the confidence of the Calcutta public, were simultaneously removed from office for various Service needs.

Worked on their present system our public hospitals must inevitably fail to provide us with anything like a continuity of consulting physicians and surgeons to satisfy the public needs. It is very true that India and the Indian Medical Service have provided for the public some great and good doctors, men such as CARTER, HOJEL, WELLINGTON GRAY, CHEEVERS, EWART, FAYRE, BOYES SMITH and others, but these men retired into oblivion and all their experience and skill was lost to India in their retirement. So it must be, as long as this system of monopolising our public hospital appointments by Service doctors is perpetuated. Calcutta cannot and never will be able to possess men of any real experience such as makes the truly expert consultant, until our public hospitals are thrown open to non-official physicians and surgeons.

We cannot understand why this unjustifiable monopoly of hospital and college appointments by men of the Indian Medical Service should be permitted to hold sway. Our public hospitals are not legally Government property. They were built and established and endowed by the contributions of private philanthropy, their working expenses are contributed to by the taxation imposed upon the people, and the public has an inalienable right to a voice in their management. We claim on behalf of the public that the opening of hospital and college appointments to private practitioners in Calcutta, Madras and Bombay would remove many serious grievances which the public has against the system which permits State-paid medical servants to block every avenue of promotion and mar every possibility of private practitioners rising to eminence in their profession. We claim also that by the present system serious wrong is being inflicted

upon the public in the education of medical students in India, as it is impossible for teachers whose time is mostly absorbed in private practice to efficiently and judiciously perform their educational functions.

We earnestly implore the Government to blot out these anomalies in the medical administration of our large cities and we should be glad to see all non-official Europeans endeavouring to remove the stigma that has hitherto most unworthily been cast upon non-official medical men, in the fact that in official-ridden India the official doctor is considered to be professionally a better man than the non-official doctor. Nothing could be more erroneous than this conclusion. Open our colleges and hospitals to our non-official medical brethren and if India has failed to knock at the door of a GULL, a HUTCHINSON, a SPENCER WELLS or a THOMPSON, men as brilliant and skilful might then be found in our large metropolitan cities."

ADMINISTRATION OF GONDAL STATE FOR 1894-95.

SELF. Self seems to be the absorbing theme of every soul; and Indian princes, as a rule, care mighty little for the tribulations of their ryots so long as their coffers are filled; but on our table lies the Administration Report for 1894-95, of the 1,024 square miles of Indian territory governed by His Highness SIR BHAGVAT SINGHJI, the Thakore Sahab of Gondal, whose life we depicted on page 183 on our eighth volume.

A young man withal (only 30 years of age) he has chosen well in his Durbar Officers and set India a noble example of self-abnegation and complete devotion to the public prosperity and individual welfare of his 5,1364 subjects, of various creeds and nationalities, scattered through five Municipalities, for out of an available revenue of only Rs. 10,89,379 he has endowed 36 scholarships, ranging from Rs. 2½ to Rs. 20 per mensem each, and actually spent Rs. 4,28,459 on the agricultural; civic, educational, medical and sanitary improvement of his territories, as well as tried to better the circumstances of his ryots and stimulate zeal towards industrial development by offering bonuses, prizes and grants-in-aid that are well worth striving for.

Thoughtful to the very extreme, he has widely differed from the opinions of the Royal (LORD BRASSEY'S) Commission, and boldly seizing the bull by the horns, has discontinued poppy cultivation and put a stop to opium consumption by issuing an order that opium eaters must not be admitted into State service, while those *habitues* already in State employ must either give up the drug within six months from the publication of the edict or *for ever* forfeit their claims to promotion; while to prevent poverty among agriculturists he has passed a decree that a judgment-debtor must accept instalments and cannot escheat the landed holdings or implements of a cultivator, in satisfaction of a debt.

Of the medical work in this state, under the care of DR. HARI BHICAJI, its Principal Medical Officer, we have already spoken on page 222 of our present volume, and we cannot but repeat that in spite of the doctor's complaint that the travelling dispensary was not quite a success, the balance of the medical work done was more than satisfactory, considering the difficulties and caste prejudices to contend with.

Judging from the magnitude of the work begun, the huge variety of undertakings got into steady progressive effect, the forward impetus given to trade and cultivation, the close bond of union brought between the Thakore Sahab and the Girmias, and the active interest displayed in the welfare of the ryots and the education of their children, the Dowry, MR. BHANUJI MEHARANI, has had no light task in assisting his prince in the management of Gondal State.

In one particular instance H. H. the Thakore Sahab has advanced Rs. 10,000 (without interest) and commodious workshop buildings (rent free) with a view to encouraging private

Industrial enterprise and enabling two copper-smiths to open an iron and brass factory in Gaudal. This reads more like a romance than a fact, as it is not within the annals of Indian history, where without the blare of trumpets, firing off of guns and advertising in all the newspapers, any ruler has before this come forward with so large a sum of money to establish two private persons in any manufacture or business that directly benefits, not the Durbar, but the subjects themselves, and these working with them.

One only thing seems strange, and that is, that with all the earnest steps he has taken to encourage education in his territories and furnish hospitals and medicines for his subjects, SIR BHAGVAT SINGHJI has not created a medical school or college to advance the noble profession of which he is an honored and deserving member.

DR. HART'S STRICTURES ON THE INDIAN MEDICAL SERVICE.

It is interesting to note how really honest critics regard MR. ERNEST HART's denunciations of the Indian Medical Service. In evidence of this we quote the words of an Indian Service correspondent of the *Lancet* and also of a service writer in the *British Medical Journal*:—

"The whole subject is one of which the complexity is hardly less than the importance, but the two things which MR. HART has plainly indicated and laid great stress on in his addresses here and in those which have since reached us are obviously urgent as matters of reform. In the first place the British Medical Service in India and the Indian Medical Service need to be brought under the same head; for while the British medical officers are demoralised and pining for want of work and want of pay, the Indian medical officers are overwhelmed with work, and get all the plums of service. Again, the present system of putting the sanitary work of India on army medical officers who are specially trained for it, and making promotion go by purely military rules, and shifting men about in the most anomalous manner, all this is destructive of real efficiency or economy. Great curiosity is felt to see what will be the result of the radical criticism from an outsider, and, with the exception of a certain minority to whom the multiplication of offices at nominal salaries is mainly a question of income, there is a general hope that the whole question may be thoroughly considered by the Secretary of State for India and by the Government of India in the direction which MR. HART suggests."

A Brigade-Surgeon-Lieutenant-Colonel, I. M. S., writes thus to the *British Medical Journal*:—

"The suggestions of MR. ERNEST HART for reconstruction and reform of the Indian Medical Service are founded, not only on his personal experience while in India, but receive the support of almost every administrative medical officer serving in India. Nor should this important fact be lost sight of, that the present system of promotions in the Indian Medical Service has given rise to feelings of discontentment and injustice on the part of several medical officers of that very service, in witness of which the *Civil and Military Gazette*, published at Lahore, wrote so long ago as December 10th, 1894. The absurdity was then pointed out, and has since been repeated elsewhere, of a "purely military medical service employed on civil work," and civil institutions staffed by military surgeons, as also of the anomalies in promotion. Correspondence in the *Pioneer* during August, 1894, after the celebrated occasion of the speech at Simla of the Principal Medical Officer of the Indian Medical Service stated that the military branch of the Indian Medical Service was rapidly going from bad to worse, and had no reason to congratulate itself on its future outlook. In short, MR.

HART's suggested reforms would set at rest jealousy, friction, and alloy diseased, all of which exist at present, proved by the expression of public opinion before quoted. The *British Medical Journal* has adverted to these matters in past issues, and the military press at home has commented in adverse terms on existing arrangements.

"It is generally believed that it is only in the civil branch of the Indian Medical Service that MR. HART's remarks have stirred up anger, for it sees in the necessary reform and reconstruction the destruction of a monopoly and the end of advancement to administrative military billets after years and years of purely civil experience, and acquisition of a competence in the latter practice."

We think the contentions of the *Record* on this subject are fully corroborated and supported by both these service writers. EURASIANS.

THE question of the socio-political position and status of Eurasians is one that is bound to engage the serious attention of the British Parliament in the not distant future. Eurasians are rising on every hand to positions of influence. Their voice will soon be heard in the highest councils of the British Empire for a distinct recognition of their rights and privileges as a "peculiar people." Their origin and growth are a natural sequence of British colonisation in India.

Socio-politically the position of Eurasians is unique. The Eurasian has really dual rights: the national inheritance of his father giving him his claim to his father's nationality, and the dower rights of his mother, both involving a principle of law admitted from the remotest era of civilisation. Every Eurasian therefore claims India as his home with all his maternal rights, privileges and duties to India as his domicile, while his paternal rights and privileges invest him with all the responsibility and duty that are summed up in the maintenance of the supremacy in India of the Government and race to which his father belongs. This then is to our mind the socio-political faith of the Eurasian. He stands between the two great races—the English and the Indian allied to both, identified nationally with the former by ties of blood, religion, education, and sympathy, and yet bound to the latter as a son of the soil.

MR. DADABHAI NAORJI, M.P., writing to us by a recent mail from the House of Commons, says:—"I have always held that Eurasians should throw in their lot with the Indians, but it is not right that they should claim themselves at one time to go with Europeans and at other times to go with Indians."

Now our honorable friend MR. NAORJI, M.P., will on a little reflection find that the advice he gives is difficult to be followed; for we would emphasize that his theory would inculcate a principle admittedly antagonistic to every nationality and religion of the world, namely, POLITICAL FRATRICIDE. The excellent race of which MR. NAORJI is a brilliant a representative is an instance in point which has held inviolate the very principle which MR. NAORJI would have Eurasians ignore. Living as the Parsees have done for the past two centuries among an alien race, and though in some measure adapting themselves to the usages and religious prejudices of the Hindus, they have never for a moment lost sight of their racial identity, not abandoned the paternal rights, social organisation, religious belief or the customs of their fathers. We need hardly dilate on this point, living as we do among Orientals who are familiar with the history of the Parsees. So the Eurasian and

Anglo-Indian, as a great Indian race, along with commendable pride to the nationality of their fathers with its great and noble traditions, its faith and its social customs as their national and indivisible heritage. We accede to the Hindu, to the Mohammedan, to the Parsee, to the fitting European population and to all the varied sections of the Indian people the religious systems that are peculiarly their own. Each has its recognized distinctive sectional religion and even racial rights and privileges allowed to it by the law and public opinion. Would we deny to the Eurasian a separate and distinctive position among these heterogeneous sections who make up the subjects of the British Indian Empire?

Justice and equity would both aid him in demanding a peculiar and unique position in India. He claims certain rights and privileges from his father's side on the one hand, his mother's on the other. His inherent instincts will ever cause him to uphold the personality of the father, the head of every family, the guardian of every home and the unit that forges the link to his claim to title of being a Britisher in every sense of the term.

PROFESSIONAL SECRECY.

"We quote the following Home truths" from the *British Medical Journal*.—DR. JESSOP, like MR. LANG, is one of the few scholars who write often and for the world without any attenuation of scholarship. It would be well if some other writers could remember that no more can be got out of themselves than they put in. In the *Illustrated News* of August 24th "the Shepherd of Arcadia" lectures medical men, and not them only, for their lackiness in respect of matters known to them in the practice of their profession. We will enter upon no defence; it is sufficient that suspicion has rested upon us. In his kindly way DR. JESSOP lays part of the naughtiness upon the "many-headed beast" the public. He tells us that the great sinner is the country doctor; yet town doctors must not be unchivalrous enough to shelter themselves under this dispensation. It is, we fear only a matter of size. Let the victim be but big enough, and urbana can bubble as incontinently as any pagan of them all. Shall we wonder if the affairs of the village SRA BOGGS are canvassed with such keenness as to drag even the village doctor into the cry? Now we are ungallant enough to hint that the error often begins by the doctor telling his wife. The partner of his bosom too often makes it a test of the loyalty of her husband that he tells her everything. It is an old saying that a secret can be kept by three men if two of them are dead, but a woman conceals—what she does not know. A wise man will make it a rule never to speak to his wife of professional matters, never even to tell her the names of those who consult him. But we will not be mean enough to let the matter lie there; if the new woman be no better than man she will stand in need of much repentance. To not a few men the consciousness of being trusted by important persons surprises their discretion, and they forget that to give up a bit of a matter of secrecy is to give up the whole; and to not a few there is the temptation to self-advertisement. No line is to be drawn between matters which seem important and those which seem indifferent. It is the habit of reticence which has to be cultivated; and the character for reticence which is to be won. He who is willing to gossip with the doctor about his neighbours will be among the first to avoid the gossiping physician when his turn comes. What saith the great lexicographer? "To tell one's own secrets is generally folly, but folly without guilt; to tell those which are entrusted to us is always treachery and treachery for the most part combined with folly."

THE VETERINARY COLLEGE.

SOME three years since a special Commission was appointed to enquire into the grounds at Belgaum, near Poona, and to report on the custody and control of the Veterinary College. To what end we wondered; as though the college was pretty thickly attended by willing students and several substantial scholarships were granted, there seemed to be no opening for the students which they should have passed out from their veterinary studies, and private practice afforded but little remuneration, if any, as traditions die hard, and it would take a month's hard reasoning to convince the average Indian that the English vet was superior to the time honored but unschooled village cow-doctor.

However, as the Government had already made excellent arrangements for the care of its own live-stock, and as this new Veterinary College was doing really good work we would naturally expect that the State would encourage the movement and stimulate healthy competition towards the acquiring of greater and sounder knowledge, by observing a strict neutrality towards the live-stock belonging to private persons, so that passed veterinary students might have the chance of earning their livelihood and recouping a portion of the money spent on their tuition. Did the Government do this, it would act both wisely and well, as success in life necessarily implies closer study to obtain success in practice, and, arguing on the well-known hypothesis of the survival of the fittest, a better class of men could be obtained for the veterinary needs of India; but it seems that the Revenue Department thinks otherwise; for it contemplates the formation of a State service for competition against independent veterinary practitioners.

The scheme, mapped out by the *Gazette of India* for the establishment of a pensionable subordinate veterinary department and a non-pensionable sub-subordinate veterinary department reads well; for the former may rise from Rs. 100 to Rs. 250 per mensem, and the latter to a maximum of Rs. 40 monthly; but this department will provide for a few (aye very few) only of the many graduates, and it is decidedly unfair that the huge remainder of the qualified veterinary practitioners should be handicapped by having to compete against men whom the Government takes under its fostering care and provides with comfortable quarters, substantial salaries, and a thousand-and-one conveniences that the independent vet must slowly rise to by dint of hard, hard work, and convincing (by cures) the people with whom he has to deal of his intrinsic worth, and complete capacity to understand and treat the maladies of four-legged and winged creation.

DOCTOR AND PROFESSOR.

A CORRESPONDENT writes us commenting on the wholesale pirating and misapplication of the terms Doctor and Professor, and the unfortunate tend of many who have no right to the claim, to prefix Dr. in place of the honorable Mr. to which (latter) they are fully entitled. His points out that strict analysis of the meaning of the terms conveys ideas rather different to those instigated by the use. The term Doctor coming from the Latin *docere*, to teach, is equally applied to those who have passed the highest professional attainments, and are (supposed to be) capable of imparting this knowledge to others. Thus we have doctors of medicine, science, divinity, dentistry, philosophy, music, law, &c. The next lower grade to doctor is bachelor, and though carrying very nearly the term doctor to an M. B., he has no special title, and he demands its application to him not as a doctor, but as a holder of any grade of qualification junior to M. D. and hence he is not a doctor, or entitled to be so addressed, as the University of London strictly speaking the term "Professor" is applied to a Doctor who teaches by means of lectures, and is not

...which, the term is equally ... and other members of the teaching ... colleges, but certainly not ... of ordinary colleges or schools. ... *British Medical Journal*—remarks: "Mr. ... with the modest aversion from special costume ... Unfortunately certain persons, whose claims ... the strongest, use the title of doctor as a means of ... and thus others are obliged in self-defence to ... the same advantages." We will not argue the pros and ... of the natural inference that the above assertion must ... but as we do not think that two or more wrongs ... possibly combine to make one right, we think that the ... every medical man, who is not an M. D. or M. B. or ... a Doctor of the learned sciences, removes the prefix ... from his door plate, cards and business-letter-heads ... for honesty and the preservation of the dignity ... integrity of the profession in the minds of ourselves and ... of the lay public."

PILES IN A POEM.

The following lines were written by a patient of DR. EDMUND PUGH, of San Francisco, whom the doctor afterwards cured of his hemorrhoids.

The Piles! Ah! I know them well,
Each feature, tho' I may not see 'em.
Old foes which fume and fret and swell
And vex and plague my perineum.
You blush at mention of a pile,
And would, perhaps, the theme avoid.
Well, then, suppose, to put on style,
We call the thing a hemorrhoid.
Tho' having an ill-omened name,
It seemed as if they might not pain us
When first as visitors they came
And took up lodgings in the anus.
But now at each succeeding bout
The plagued pains appear distincter,
And there can be no longer doubt
Of their relations with the sphincter.
You ask me by what obvious sign
One may with certainty detect them.
Well, I can only say that mine
Are like a hornet in the rectum,
Which, having wandered from the way,
And angry at the situation,
Stings right and left, the while it may,
And tortures one in defecation.
Avaunt! It is a vulgar rhyme,
Yet stay, there must be means to cure 'em.
Oh, yes, if you but give them time
And very patiently endure 'em.
There are a thousand cures, you know,
All certain sure as dead-shot candy:
The well to buy a score or so
And lay them by to have them handy.
And when the hornet's rage is spent
And things assume their wonted quiet,
The cure, tho' it may not prevent,
Will surely quell the painful riot.

MEDICAL MATTERS IN HYDERABAD.

The hospital situated in the centre of the town, is small and ill arranged, but in many ways is more adapted to the treatment of the sick than a larger one would be. A number of small private wards, in which the women are treated, are visited upon by their relatives and friends in a common courtyard. These privileges go a long

way towards inducing patients to seek in the hospital for proper treatment. Chloroform is administered in a most methodical, systematic and scientific manner and everything is carried out with scrupulous care and in great detail under the personal supervision of Dr. Lawrence, the Principal of the Hyderabad Medical School. The patient being stripped to the waist as he more easily watch his respiration, four students take charge of him. The first student announces aloud, so that all present can distinctly hear him, all the phenomena and the exact time of occurrence from the beginning of the administration until consciousness returns, the variations of pulse, respirations &c. The second student (the clinical clerk) writes down all these particulars on specially arranged forms. The third student stands on the right hand side of the chloroformist with a drachm measure-glass and a bottle of chloroform which he measures out as required. The fourth student, as the administrator himself, takes a cone of canvas (stiffened at the sides with cane), at the apex of which is a plug of clean cotton wool upon which he pours the chloroform, drachm by drachm, every minute at first, until struggling commences then half a drachm every 45 seconds. DR. LAWRIE, who looks to the respiration for a warning of approaching danger and not the pulse, is present the whole time, controlling and checking any inaccuracies during the administration, or in recording the phenomena &c.

DR. LAWRIE has, by his tact and enthusiasm, created a native medical school which gives no mean result in what was till recently, the most retrograde of the states of India.

PREVENTION OF RABIES AT THE PASTEUR INSTITUTE.

In a recent number of the *Annales de l'Institut Pasteur*, M. H. Pottevin gives the statistics of preventive treatment of hydrophobia in Paris during 1894. The total number of persons treated was 1,392. Of these, 13 died of hydrophobia, but as in 5 of the fatal cases the first symptoms showed themselves within a fortnight of the last inoculation, these should be deducted. Three cases in which hydrophobia developed whilst the patients were under treatment were also excluded. This leaves a total of 1,387 persons treated, with 7 deaths, a mortality of 0.50 per cent. The corresponding figures for the eight preceding years are as follows: In 1888, 2,671, persons were treated with 25 deaths, or 0.95 per cent.; in 1887, 1,770 with 14 deaths, or 0.79 per cent.; in 1886, 1,622 with 9 deaths, or 0.55 per cent.; in 1885, 1,830 with 7 deaths, or 0.38 per cent.; in 1890, 1,540 with 6 deaths, or 0.32 per cent.; in 1891, 1,559 with 4 deaths, or 0.25 per cent.; in 1892, 1,790 with 4 deaths, or 0.22 per cent.; in 1893, 1,549 with 6 deaths, or 0.36 per cent. Of the 1,387 persons treated 1,161 were French, and 226 belonged to other nationalities. Among these Great Britain heads the list with 125; Greece and Spain come next, though *longo intervallo*, with 26 each; then comes British India with 18. Belgium next 10, Turkey 7, Holland 2, Russia and Egypt 1 each.

LOUIS PASTEUR.

BORN at Dole in France in 1822, LOUIS PASTEUR was first brought up as a chemist, but having a leaning towards medicine, he entered the college at Paris, where in 1847 he took his degree of Doctor, after which he turned his close attention to biology, in which he made several valuable discoveries, especially as regards the laws of fermentation, and first brought himself into distinction by his researches on zymotic diseases in silkworms and domestic animals. His frequent dives into the mysteries of nature so infused him with the theory of the creative value of atmospheric virus in *legion stercoris* that he commenced and, in spite of the little

oppositions he met, continued a series of investigations round which raged a furious controversy regarding the ethics of vivisection; but he persisted in his self-imposed task until he solved the deadly conundrum of rabies and gave the world a ready means of successfully combating the hitherto (claimed to be) insensible hydrophobia. The Paris Pasteur Institute and a number of branches in various parts of this world remain to testify that though this year gathered this grand old man (at the age of 78 years) into the realms of the great unknown, he has left an indelible mark behind and hundreds live to thank him for snatching them from the jaws of a horrible death, while the faculty of medicine can never sufficiently thank him for the immense service he has rendered to mankind by showing them the methods by which they can readily arrive at the etiology of many an infectious disease and find means for its prevention and cure.

THE HORRORS OF A DOCTOR'S LIFE AS PROVED BY THE JAMES CASE.

Her lover sent Miss JAMES for treatment to Dr. LEHMAN, who, suspecting appendicitis or typhoid fever, advised her to lay up at a quiet boarding house, where he visited her several times; but as she grew worse, he called in Dr. E. E. KING and performed an operation, six days after which the girl died. The lover creating some ugly rumours about the case, an autopsy was made, disclosing that though the direct cause of death was septicaemia, pregnancy had existed, and the cervix uteri had been torn, while removing the contents of the womb. In consequence Dr. LEHMAN stood charged with the serious crimes of procuring an abortion and thereby causing the death of Miss JAMES; but the inquest completely acquitted him from all blame by bringing out the facts that the girl being prostrated with severe rigors, rapid pulse, high temperature and a very offensive discharge *per vaginam*, Dr. LEHMAN sent for Dr. KING in consultation, when it was decided that the intense gravity of the symptoms demanded an immediate evacuation of the uterus. Miss JAMES was accordingly chloroformed, her cervix dilated with great difficulty by fingers and steel dilators and a putrid foetus, dead at least a fortnight or three weeks, was delivered, appropriate treatment was carried out, but she died some six days after the operation.

POISONING AS A FINE ART.

MOHAN SINGH, his brother and a woman, SADAKUR, went to Chindwara, where under the plea that they were Thakurs, forced from Panna by debt, they started operations with stramonium and reaped a rich harvest by drugging and pillaging whole villages; but nemesis was on their track, as growing careless with the callousness of undetected crime, after poisoning some 80 persons, they began to openly wear some of the plundered jewellery, and attracting the close attention of the myrmidons of the law they were pounced upon and sentenced to fourteen years' penal servitude. Their *modus operandi* of averting suspicion from themselves was to curry favor with their neighbours and, offering to grind their wheat, secretly mix dhatura meal into the flour, which was then cooked by the unsuspecting victim, and all who partook of this poisoned flour became more or less insane when MOHAN SINGH and Co. eased them of their valuables and let the blame of the drugging fall on the innocent cook.

THE DISCOVERER OF MATCHES.

THOMAS has just died at Saint Lothaire, in the Jura, a country doctor, named Sauria, aged 84, said to be the inventor of lighter matches. In 1831, when a pupil at the College of Dole, Sauria had the idea of making matches with saltpetre of potash, phosphorus, and sulphur. But he was unable to patent his discovery, as he lacked the 1,000 francs necessary to do so. He talked with M. Moit, his professor of physics at the College, and that gentleman lectured on the subject some time after when visiting Germany. The

German remembered the episode, while the French, who came back to France and were called *allumettes*. When M. GRÉVY was President of the Republic, Dr. Sauria, who a worn-out old man, got a Government appointment as the keeper of a tobacco shop.

FILTERS FOR INDIA.

It is a universally accepted sanitary axiom that "pure water is synonymous with "good health." Pure water is one of India's crying needs. A well-arranged water supply is an urgent desideratum in every Indian Municipality. But the machinery and plant for a perfect water supply cost prodigious sums of money, and these, our village hamlets cannot afford. Clean, protected wells are the next means of protection from preventable disease. Better again than unsafe "protected" wells are FILTERS. Can India be provided with an efficient easily worked and cheap FILTER? We read now-a-days of filters that defy disease germs and make drinking water absolutely safe from all sources of infection and contamination? But all these filters are too expensive for general adoption in India, and what the medical profession throughout this country feels as a pressing need, is a really good, cheap domestic filter. Surely mechanical and sanitary engineers are not so deficient in constructive genius as to allow so needful a commodity to be vainly sought after in so promising and lucrative a field as the Indian market? Who will construct a cheap and reliable filter for India?

THE NATION'S DRINK BILL.

THE Parliamentary return submitted by Sir F. SEAGER HUNT for 1891 shows that the increased consumption of chicory, cocoa, coffee, tea and non-alcoholic beverages had far outstripped that of intoxicants, for though the value of the latter reached the enormous figure of £138,737,828 for the whole of Great Britain and Ireland, and though the expenditure on beer had gone up £408,002, spirits had decreased by £237,767, and wines by £287,286. Thus shewing a net decrease of £287,286. This augurs extremely well for the moral progress of a nation that used to spend more than double the above amount on their annual liquor bill.

A PRIVATE SANITARIUM FOR MUSSOORIE.

Dr. John Morton M.D. of "West Lynne" Mussoorie, who has been most successful in practice in that delightful hill station, has taken the commodious house known as "Mayfield", to which he has made many useful additions and alterations, so as to fit it for a private hospital. It is now complete and ready for the admission of patients and invalids. We congratulate Dr. Morton on his enterprise and commend his zeal to the support of our brotherhood.

THE RECORD SECTION OF THE COATES MEMORIAL FUND.

WE now desire to appeal in a special manner to our brethren to send in their subscriptions to the "RECORD SECTION" of the Coates Memorial Fund, and we would be extremely grateful to see a large number of those who knew Dr. J. M. COATES, send in their amounts, no matter how small or how large, at once. We shall publish the list of donors when it is sufficiently large. Surgeon-Major N. O. Hodgkins M.B., Medical College, Calcutta, will act as treasurer to the Fund and to him all subscriptions should be sent. Messrs. Grindlay & Co. Calcutta, agree to be the bankers of this section of the Fund.

DEATH FROM A LUNATIC'S BITE.

A DANGEROUS lunatic being arrested by Inspector Fitzgerald last week, orders were issued to remove him to the Bolnada native lunatic asylum in Bhowanipore, whither two native constables were conveying him to a gallery, when he bit one of them severely on the right arm. The injured man was removed to hospital, where he died, two days after, "perfectly used."

INDIAN MEDICAL PROVIDENT FUND.

In our last number we recorded 85 names as willing to join the above fund. We now have pleasure in noting the following additions:—S. Chakraborty, M.D., L.R.C.P. & S. (Edin.) Patiala; Surgeon-Major E. B. Wrafter, I.M.S., Dehra Dun; Surgeon-Captain G. H. Campbell, S.A.S., I.M.S., Calcutta; Surgeon-Captain W. Church, F.R.C.S., S.A.S., I.M.S., Poona; Surgeon-Captain G. H. King, S.A.S., I.M.S., Bolaram; Assistant Surgeons Jogendranath Biswas, L.M.S., Jhelum; E. H. Thomas, M.B., L.R.C.P. & S., Dehra Dun; F. J. Daley, I.M.S., Dehra Dun; Ham Narayan, L.M.S., Delhi; H. Day, I.M.S., Saltpore, E. B. S. By.; A. H. MacGregor, I.M.S., Bombay; J. T. Neill, I.M.S., Aden; T. H. Aquino, L.M.S., Gaidag; J. A. Bailey, I.M.S., O. Fox, I.M.S., P. Victor, I.M.S., A. Robinson, I.M.S., E. A. Picachy, I.M.S., Camp Jalala; Durga Prasad, C.M.S., Dehra Dun; P. V. R. Pillai, C.M.S., Kykolor; J. Eschkei, Mbow; U. R. Dubay, C.M.S., Wardha; A. M. Lazarus, C.M.S., Mandalay; Bisto Mohun Bosa, C.M.S., Shwegyn, Upper Burma; Nehal Chand, C.M.S., Majulghar, Assam; Kalkhuree Jivanji, L.M.S., Secunderabad, Deccan; G. P. D'Souza, C.M.S., Amraoti; M. Iyaswamy Pillay, C.M.S., Akidli; Asst Surgeons. L. N. Choudhuri, L.M.S., Balaghat; A. Rodrigues, I.M.S., C. M. D'Souza, I.M.S., Quetta; Gunga Gobinda Sarkara M.B., Noakhali; Dr. C. W. Roberts, Civil Surgeon, Tharawaddi; V. S. B. Mudaliar, C.M.S., Channagiri; D. Dahyabhai, C.M.S., Rajkot; Asst. Surgns. H. F. G. Kinsley, I.M.S., Aden; J. O. Bailey, I.M.S., Amritsar; Dr. S. J. Mullens, S.R.I. Srivilliputur. This makes 102 names and completes the preliminary list.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

THE following have joined the Indian Medical Association since our last publication of names:—Charles F. Parker Assistant Surgeon I. M. S., Webb St. Fitzroy, Melbourne; H. C. Banerjee C.M.S. Civil Medical Officer, Gyoblugonk, Thariawady District; Hemadry Daraswamy Pantulu C.M.S. Civil Hospital, Tharawady; George E. Claxton L.R.C.P. and S. Edin. Nainital. M. Iyaswamy Pillay C.M.S. Akida, Godawari District; Miss M. E. Bryan M.D. Mission Hospital, Bareilly; Z. Feldstein, M.D. Calcutta; Surgn.-Capt. George Edmond King, S.A.S., I.M.S., Bolaram.

SHORT ITEMS.

In England no certificate of the cause of death is recognised, unless given by a practitioner whose name is on the *Medical Register*. A person merely present at the time cannot give a certificate of the cause of death; and if an unregistered medical practitioner gives a certificate, it is regarded by the registrar merely as a part of the information tendered by the "informant."

It is said that donkey lymph has been used for vaccination purposes with great success in the Punjab. According to a contemporary, people who have imbibed donkeys' milk in their childhood carry through life a certain wrong-headed argumentativeness, something akin to the stubbornness of the ass.

The *Times*, discussing the Bluebook on sanitary measures in India, refers to the ravages of contagious diseases in the army, and says it would seem to be one of the first duties of Government to consider how far their responsibilities to the Army and nation have been adequately discharged under the present system.

Malcolm Morris of the *Practitioner* says the *Indian Medical Record* is a handicap for writing against the opium question. Unable to give an honest blow itself, the *Indian Medical Gazette* reproduces in its columns, Malcolm Morris' article in extenso. Bravo!

Mr. John Elliot, Meteorological Reporter to the Government of India, who arrived in Srirangar on the 30th Sept. is consulting Dr. Mitra, Meteorological Reporter to the Cochin State, on the feasibility of opening one or two observatories in the higher altitudes near Skardu and Dera.

Dr. William Hotchkiss died in St. Louis, Mo., April 1st 1895. A letter received from his old Virginia home over a year ago said that he was born there in 1736. His Masonic record has been traced back one hundred years, showing conclusively that he was at least 121 years old.

The Government of India has been pleased to continue the employment on the personal staff of the Lieutenant-General Commanding the Forces, Madras and Bombay, of the Military Assistant-Surgeons formerly authorised for the army headquarters of these commands.

Some touchy I.M.S. surgeons threaten to resign the British Medical Association unless Dr. Ernest Hart's sweeping denunciations of their service be rescinded. An old woman of a Professor of the Calcutta Medical College, an I.M.S.-man of course, asks that Hart be beheaded.

We note with regret that the "Social" column of the *Indian Daily News* (of which a service doctor is a shareholder) is again being used for the surreptitious advertisement of Service doctors.

The Terrol Company, have been awarded a gold medal for Terrol, at the World's Exhibition at Amsterdam.

The new regulations of the Ministry of Education admit women to the University at Berlin to study medicine, dentistry and pharmacy.

Professor Haffkine is now on his way to Paris. His intention was to lay the results of his Indian labours before Pasteur. Unless spiritualism come to his aid, Haffkine must wait till the "Sweet by and bye."

A strong effort is to be made in parliament for the renewal of the C. D. Acts. The devil is in power if the abomination succeeds.

Dr. Soltan will leave Ootacamund about the end of next month, having been offered and having accepted the post of medical missionary in a London district.

Surgeon General Longmore A.M.S., the well known writer on Military Surgery, died in London on the 2nd October.

The death is announced of Surgeon-General Irvine, who was for many years Civil Surgeon of Alibabad.

Members of the Indian Medical Association, who have not paid their subscriptions, will oblige the Treasurer (Surgeon-Major H. C. Medghia, S.A.S., Medical College, Calcutta) by sending them in without delay.

Subscribers in arrears with their payments to the "Indian Medical Record" will oblige the Proprietor by remitting their dues as early as possible.

Current Medical Literature.

MEDICINE.

The pathology and treatment of an ordinary bilious attack.

DR. ROBERT SAUNDY, of Birmingham points out, that in ASCHESON'S time (1864), the physiology of digestion and the pathology of the stomach were so ill understood, that what appeared him a mere collection of symptoms, dependent upon deranged function is, nearly to us, the effect of catarrhal inflammation of the mucous lining of the stomach and duodenum. The term "bilious" is very loosely applied in common parlance to signify headache, acidity, flatulence &c. Often enough the symptoms are of nervous origin and have nothing to do with a proper bilious attack. "How to give liver."

a very common question, conveys an entirely different impression to the patient and is often the result of inadequate pathological knowledge. The primary seat of the mischief lies, NOT in the liver, but in the stomach, as the pathological basis of the symptoms presented, is the inflammatory condition of the gastric mucosa, from the ingestion of friable and indigestible food.

The case of Alexis St. Martin illustrates a very important point, viz., that a patient may be in apparent good health and yet suffer from bilious attacks. He was noticed that after drinking about spirits thrice for eight or nine days, Martin usually complained of tenderness at the pit of the stomach, weight, etc. His tongue was thick coated and his countenance yellow. In all other respects he was apparently quite well and healthy. His appetite was very good. The attack of biliousness was caused by the sudden accumulation of the stomach.

...the patient was not much out of sorts.

The treatment consists in keeping the inflamed surfaces of the mucosa apart by means of bland easily chewed and highly non-irritating diet. Vegetables must be interdicted owing to their containing starch, also sugar, cheese, acids, fried meats &c. Spirits and wines must be prohibited, but clear with mineral water is a harmless drink. During convalescence the light meats, suitably cooked and well masticated, are well tolerated (even by an inflamed stomach) whereas starchy foods cause flatulence. DR. SAUNDY believes in stimulating the normal mechanism by which the stomach empties itself by means of blue pill—thus:—two 5 gr. blue pills are given on two successive nights. In the morning a breakfastcupful of warm water containing $\frac{1}{2}$ of Carlsbad salts is sipped; while before each meal a powder consisting of Bismuth, Rhubarb, Sodium Bicarb. and pulv. Cinnamon is taken, suspended in a little milk. If these means fail to cure a bilious attack in 3 or 4 days our diagnosis must be reconsidered. We must look for something in addition, or something else, e.g. acute gastric catarrh, with a clean tongue.

Treatment of Diphtheria.

DR. WHITE, after reporting a series of cases treated at the Willard Parker Hospital, draws the following conclusions:—

1. That frequent washing of the air-passages attacked by diphtheria lessens the duration and amount of diphtheritic membrane.
2. The addition of antiseptics, of sufficient strength to be germicidal, to the irrigating fluid, is irritating to the mucous membrane, thereby causing extension and persistence of false membrane rather than the effect desired.
3. The addition of antiseptics to the irrigating fluid is liable to cause system poisoning and disagreeable complications from the swallowing and absorption of some of the fluid used,—e.g., the two bichloride cases cited above.
4. Spraying the throat (also the pernicious treatment of swabbing), whatever solution is used, can have no good effect as the parts reached by the spray must necessarily be very limited, excepting, possibly, in the hands of an expert. Furthermore, the spray cannot be used with young children, as anyone can testify who has tried it. This is especially true of some solutions where it is necessary to use a glass syringe.
5. Frequent cleansing of the throat and nasal cavities with a bland solution, such as plain warm water or normal salt solution is easier of application, is more agreeable to the patient, and does all that any antiseptic solution can accomplish, either upon duration of the membrane or the period of isolation.—*Gillard's Med. Journ.*

Dry Gangrene after Snake-Bite.

DR. CAPTAIN F. J. PORTER, A. M. S. writes in the *British Medical Journal*:—"With reference to the case of dry gangrene after snake bite reported by Dr. M. S. DOBBS in the *British Medical Journal* of July 6th, I would like to mention that a healthy Musselman boy, aged about 17, came to the Indian Army Hospital about three weeks ago with typical dry gangrene of the terminal phalanx of the middle finger of the left hand. He had been stung by a scorpion about ten days previously. The tip of demarcation was well marked above the middle of the second phalanx. It was let alone until the separation had extended to the base, and then the

bone was cut through, a little higher up, having been with a very useful stump. In this case I suppose that the gangrene had been stopped in the terminal phalanx on account of the pressure on the blood-vessels of the inflammatory process poured out at the seat of inoculation. The gangrene was also strictly local. From the extent of the gangrene in Dr. DOBBS's case, I should be inclined to think that the barbed wire ligature was the cause of the extensive gangrene which resulted.

Causes of Sexual Debility in the Male.

MANY authors attribute this condition to masturbation, or to excessive venery or to organic stricture or to atrophy of the testes, solely, but STUART contends that these play but a secondary part in the imperfect erections and premature emissions which he thinks are usually, if not entirely, due to irritability or hyperesthesia of some portion of the urethra. He also finds that varicocele plays an important part, and the history of tuberculosis, syphilis and gonorrhoea should all be taken into consideration when summing up the causes that lead to sexual debility and the connubial misery or mental agony it occasions.

Biliary Cirrhosis in Children.

FROM several clinical observations published by them, in extenso, GILBERT and FOURNIER concluded that though all the symptoms observed in the adult were present in biliary cirrhosis in children or commencing in childhood, still the hypertrophy of the liver was not very great; but the spleen was so conspicuously enlarged as to create error in diagnosis, and in many instances osseous nutrition was so deranged as to cause clubbing of the fingers and enlargement of the ends of the femur and tibia.

Rheumatic Fever and its Epidemiological Relations.

NEWHOLME shows that dampness does not cause or favor rheumatic fever, although causing so-called "chronic rheumatism." Muscular rheumatism is probably closely related to acute rheumatism, which is a specific infectious disease, not so much due to heredity as is supposed, and probably not produced by the influence of a meat diet. In the years when it is epidemically prevalent, the ground water is low and exceptional scarcity of rainfall prevails. A dry soil appears to favor and it would seem that the conditions of soil producing malaria are exactly opposite to those favoring rheumatic fever.—*Lancet*.

Paroxysmal Hemoglobinuria.

BY means of repeated experiments on the human subject CHAFFARD has proved that although the paroxysmal hemoglobinuria produced by exposure to intense cold presents the prodromal symptoms and premonitory albuminuria of a general attack, still it materially differs from the typical affection by the blood clot refusing to redissolve, and he therefore concludes that in addition to exposure to cold some central nervous disturbance (whose path is uncertain) is essential to the starting point of the chemical processes that result in an attack of hemoglobinuria.

Scotch Heart.

FOUR cardinal rules with regard to diet: 1. There must never be less than five hours between meals. 2. No solid food is ever to be taken between meals. 3. All those with weak hearts should have their principal meal in the middle of the day. 4. All those with weak hearts should have their meals as dry as possible.—BALFOUR (*N. Y. Med. Rec.*)

SURGERY.

Radical Cure of Hernia.

According to pathological and anatomical grounds, FERGUSON takes exception to the practice of removing the sac in operations for hernia, and claims to have effected quicker and radical cures by the following methods:—*Inguinal Hernia.*—Between 1 to 1-inch incision parallel to POUPART'S ligament over the inguinal canal to the pubic spine and divide all the structures above the canal and between the internal and external abdominal rings. Dissect out the sac, loosen its neck from its attachments, transect it several times in a proximal direction with a suture that has been firmly secured to the distal end, and passing the needle from down up through all the structures in front of the subperitoneal tissue, draw it out 1 inch above the internal abdominal ring, and after pulling on the suture so as to throw the sac into folds and bring the parts together, fasten it to the external oblique muscle. Pass three inversion-sutures, from without inwards, through the deep fascia, parallel to Poupart's ligament, and approximate all the muscular aponeuroses by 3 or 4 mattress sutures, from below upwards, in such manner as to bring the lower and external structures over and in front of the upper and internal structures. Lay the cord upon the external surface of the external oblique muscle and close the skin wound. (3) *Femoral Hernia.*—The operation is on the same lines as above, except that the sac is folded upon itself and fastened within the aperture of the crural canal, care being taken to cut away involved omentum and to cover the raw stump with peritoneum before returning it to the abdomen. Should, however, the sac be too small to close the hernial opening and approximate Poupart's ligament to the pectineal fascia, a periosteal flap may be utilized or a flap of the pectineal fascia and muscle should be raised and stitched to form a buttress.

Gonorrhoeal Immunity.

1. GONORRHOEA is a self-limited disease, recovery following after a varying length of time, without any treatment other than plumes, baths, and hygiene. 2. Abortive treatment does not succeed rapidly and fully until the period of acute inflammation has passed. 3. A patient, either male or female, apparently, though not really cured, is capable of transmitting a subacute gonorrhoea—that is, the colorless drop of secretion is capable of inoculation if it contains a few gonococci. The author consequently believes that the gonococcus during its evolution modifies its culture media, i.e., the urethral mucous membrane. It continues to grow there but becomes more and more attenuated and latent until it finally disappears. Unless this is true, a gonorrhoea, untreated, would last indefinitely, the cocci multiplying and re-inoculating themselves in the infected urethra continuously. It is at the time when the virulence begins to diminish that abortive treatment succeeds. If, on the other hand, this attenuated gonococcus comes in contact with a healthy mucous membrane in another individual, it is immediately rejuvenated, prospers, and produces acute gonorrhoeal symptoms, since it finds there a suitable culture medium, which is not exhausted with that from whence it came and where it was about to die. The objectors to this theory say: "If you admit that the role of the culture-medium is thus superior to that of the microbe, how can you explain acute attacks in men having gleet? How can their exhausted mucous membrane become re-inoculated?" GUARD believes this re-infection is impossible in cases where the gleet discharge continues long. He, however, reserves his opinion regarding this form of relative immunity until further facts are procured. JAMIN AND GUARD.

Diagnosis of the Intestine after Rupture of the Abdomen.

THE absence of free fluid in the (Morley). 1. Frequent and uncontrollable vomiting. 2. The appearance of peritonitis, if lesions of the kidney, bladder, liver, and spleen can be excluded. 3. Spontaneous pain in the abdomen is itself itself of much diagnostic value.

Regarding the advisability of operating in these cases, the author says: 1. If there is unmistakable evidence of rupture of the intestine, immediate laparotomy is indicated. 2. Exploratory laparotomy, after confusion of the abdomen is usually to be avoided; in uncertain cases, expectant treatment should be adopted (Mety). 3. If soon after the injury (twenty-four to thirty hours) there are signs of sepsis, operation is contra-indicated. A low temperature with marked constitutional symptoms is an especially unfavorable condition. 4. Rapidity and delicacy are essential in operating for rupture of the intestine, especially if peritonitis is present. Therefore make a long abdominal incision, rapid, systematic examination of the intestine, avoiding rough tearing or handling; and if possible to avoid it, do not resect the intestine; employ simple Lambert sutures, or at most a wedge-shaped resection of the injured portion of intestine, and close with a simple running suture including the muscular and serous coats. Flushing the abdominal cavity with antiseptic liquids is to be avoided.—BENNETT.

On the Treatment of Fractures, near a joint, by rest, aided by Massage and Passive Movement.

DR. MILLER draws attention to the unsatisfactory results obtained by the present system of treating fractures near joints.

The chief cause of these unsatisfactory results he believes to be the long period of rest maintained, during which time the damage done to the joint is ignored. The rest alone would not cause ankylosis, but when a fracture takes place near a joint, there is effusion of blood and serum into and around the joint. If this state of matters be left to themselves it is quite evident that adhesions and contractions would form, which materially interfere with the usefulness of the limb.

DR. MILLER goes on to shew how this difficulty can be met, by treating the two injuries simultaneously. Rest for the fracture, and massage and movement for the joint, which can be effected by opening the splint twice a week, when the limb should be carefully massaged and the joint worked with every precaution to prevent movement of the fractured surfaces.

The advantages of this combination of rest with massage and passive movements are:—(1). Complete rest is provided for the fracture. (2). Swelling and effusion are got rid of more quickly by the massage. (3). Adhesions are prevented by passive movements; and (4) union of the fractured surfaces is probably facilitated by the massage.

Fistula in Ano.

1. NEVER sever the sphincter at more than one place at the same operation, no matter what the complications may be, otherwise incontinence is sure to follow. 2. Unless all the channels are followed up and laid open, the operation will fail of its purpose. 3. Fistula resulting from tubercular abscess must not be operated upon if there is sufficient tissue destruction of long to produce lasting incontinence, even when the fistula is opening over a painful abscess of the sphincter; then it should be divided at any stage. 4. After laying the fistula tract open the rectum must be made

to the lower part of the wound, and the edges of the wound will then close. It will throw out a more healthy granulation than tends to bridge over and close the wound, leaving a surface at the bottom, thus leaving a healthy granulation. 5. When the fistulous tract is not too complicated, it should be dissected out entire, and the wound brought together, beginning at the bottom, with continuous suture and approximating the surfaces in subcutaneous layers until the whole wound is closed.—BACON.

Indications for Resection of Skull.

1. We are called to make a resection in complicated fractures, when it is feared that infective matter has entered the wound, or when it is known that the cranial cavity has been penetrated by some dirty knife or instrument. 2. In fractures to which an aseptic dressing has been applied. 3. When we suspect a fracture of the inner table or for depressed fractures. 4. For the removal of foreign bodies, bullets, knife-blades, etc. 5. For cerebral hemorrhage, with signs of compression, and for the ligation of the middle meningeal artery. 6. For fractures which have subsequently become infected through carelessness on the part of the surgeon or attendant. 7. For tumors of the brain, abscess of the brain, epilepsy, and chorea when due to trauma, syphilis, tuberculosis.

Laparotomy in Tuberculous Peritonitis.

COMMENTING on the rapid involution of tuberculous nodules after laparotomy, NANOTTI and BACCHOCCHI conclude that the beneficial effect is produced not by the antiseptics applied to the peritoneal cavity, but by the shock of the operation setting up inflammatory reaction of the peritoneum, whose absorbing power is thereby increased and a strong impulse given to phagocytosis, connective tissue formation, degeneration of the cellular elements and vascularisation of the tuberculous nodules with rapid and successive fibrous transformation.

Surgical Brevities.

THE indiscriminate use of antiseptic injections cannot be too strongly condemned, since many fatal results have immediately followed its practice. Immediate washing out of the pleural cavity after operation, for ordinary empyema, is always an inadvisable and hazardous procedure, and is only permissible at later periods when practised with the greatest caution.—WHITE.

Stricture of the Urethra is most safely healed by gradual dilatation repeated every third day. In continuous dilatation a filiform bougie can remain three days, after which other instruments can be used.—HOBWITZ.

CLEANSE Varicose Ulcers with sodium bicarbonate, apply methyl-violet solution, cover with absorbent cotton, and give even support to the tissues by bandage.—SUMMERS.

Early application of strong nitrate of silver solution is useful in Bed Sores.

Storing the Hypodermic Syringe is apt to spoil the leather packing.

Carbolic Acid should be applied very sparingly to open wounds, especially in young and old subjects.

There are three chief points to be considered in effecting Intestinal Anastomosis, or in suturing a wound of the intestine: 1. That adequately broad and sufficiently wide surfaces of healthy intestine should be in contact. 2. That though it is advisable to exclude the mucous membrane from the stitches, the fibres of the submucosa coat must always be included. 3. That the operation should be performed as rapidly as possible.—BROUHAU.

ABOUT the earliest symptom of Prostatic Disease, is an increased frequency of urination, especially at night. This symptom very often precedes any enlargement that can be discovered either by rectal examination or by the use of the catheter.—KEMM.

Auto-inoculation of Chancre.—In the first case the seat of the chancre was inoculated in the right scapula; in the second, the chancre was on the inner side of the eyelid, which the patient had rubbed continually; as a particle of iron shaving had lodged in the conjunctival cul-de-sac; in the third, it occurred in the folds of the prepuce.—KOLLY.

OBSTETRICS AND GYNECOLOGY.

Deep Incision of the Parturient Cervix for Rapid Delivery.

DR. J. CLYTON EDGAR, in a long and well-illustrated paper, deals with the question of the scope and usefulness of deep incisions of the cervix in parturient patients with eclampsia, a method of operative interference by means of which Dithrasen has obtained brilliant results, having in thirty-five cases saved all the mothers, and all but two of the infants. Three cases are reported, in two of which the above-named operation was performed, whilst in the third the deep cervical incisions were accompanied by mechanical dilatation. In the last-named case the mother and twins were saved; in the former two instances the mother died in one, and the child was saved in both. In the case which proved fatal to the mother an autopsy was obtained. DR. EDGAR believes that the operation should only be undertaken when the entire supravaginal portion of the cervix is dilated, i.e., when the defective dilatation is confined to the vaginal portion. The field for the operation is a limited one, and the method of treatment must be regarded as serious. It is not possible yet to say what the ultimate value and real danger of the incisions may be, for sufficient cases have not been reported. The risk of septic infection may be greatly lessened by strict surgical cleanliness. Hemorrhage is not much to be feared if the incisions are deeply made, still it is well to introduce a tampon of iodoform gauze into the genital tract. A useful bibliography accompanies this paper.—*Amer. Jour. Obstet.*

Twin Pregnancy with Fetal Mummification.

DR. ULECIA gives a summary of a case of twin confinement with mummification of one fetus, reported by DR. CARRERA of Habana. The mother, a multipara, 23 years of age, showed purpuric spots at the fifth month of pregnancy. Under treatment by perchloride of iron these disappeared but later signs of ante-partum septicemia occurred. Notwithstanding treatment, the fever continued, and labor supervened prematurely. After the birth of a living fetus, there was placental retention with syncope. The placenta was extracted manually, and with it came away a mummified fetus of six months. The placenta was single, and gave insertion to the two umbilical cords.

Rectal Examination of Pregnant Women.

W. H. BECKMAN has tried this method with great success in 100 parturient women, the details of pelvis and cervix being easily made out. The length of the pregnancy and state of the bladder could not be determined in 7 per cent. of the cases, and the fontanelles and sutures could not be felt in 23 per cent., but this was of less importance, since the position of the fetus could easily be detected by external examination, and especially by auscultation. It was always possible to distinguish the occipital from the frontal portion of the head. The advantage of rectal examination is that infection through the genitals is avoided, the only objection

being the most common method through the vagina may become necessary, and the following notes through the external os, although the latter practice is not recommended, since the external os does not contain specific microbes. The author considers vaginal examination of great value to midwives, enabling them to determine if the presence of an obstetrician will be necessary. DEWEES's experience in the Leipzig Obstetrical Clinic showed that students instructed in this method of examination could determine all the necessary details without recourse to vaginal examination. RIES believes that midwives should be forbidden to make examinations through the vagina, as their duty is only to assist at normal births. KROEMER is inclined to permit vaginal examinations only (1) when it is difficult to determine through the rectum what part of the fetus is presenting, (2) when the midwife is not able to bring about relaxation of the cervix, (3) when the pains last for more than two hours.

Calculus in the Fallopian Tube.

GILLES describes and figures an S-shaped calculous concretion, nearly one inch long, in a diseased tube. It was composed almost entirely of phosphate of lime. On pressure it was soft and yielding. The patient had been an invalid for many years, and suffered chiefly from some gastric disorder. She had also acquired the morphine habit, subsequently to an attack of rheumatism, several years before operation. The pelvic trouble is reported as very acute, only beginning about ten days before the parts were removed, the patient catching cold. The temperature at the time of operation was 106°F, and the patient was in a state of extreme collapse. An exploratory laparotomy was performed, and the right tube and ovary were removed. The patient grew rapidly worse during the brief operation, and died seven hours later. No necropsy is reported. There was hydrosalpinx, the tube being also inflamed and the ovary involved. —*John Hopkins' Hosp. Rep.*

The Hysterical Breast.

This is a condition which GILLES DE LA TOURETTE considers of much importance, not only because it is a well-defined manifestation of hysteria, but also from the fact that it has given rise to errors of diagnosis and needless removal of the organ. It consists in a temporary enlargement of the breast, with considerable hyperaesthesia of the skin covering the organ. This hyperaesthesia is liable to vary, becomes much more marked during menstruation; there is then also more swelling, and considerable pain is complained of. On palpation at such a time it is possible to perceive one or perhaps two tumour-like masses in the substance of the breast, about the size of a hen's egg, but which are not painful, the hyperaesthesia being cutaneous. The affection is often of long duration, more especially in those cases where there is faulty menstruation, as often happens. It seems to depend on a hysterogenous band of hyperaesthesia at the level of the breast, which induces an oedema of the connective tissue of the gland. In this way are produced the local swellings, and even patches of white, pink, or violet under the skin. —*Brit. Med. Jour.*

Indications for Induction of Abortion.

Absolute Indications: 1. Uncontrollable vomiting of pregnancy. 2. Incurvation of the gravid uterus. 3. Obstruction of the pelvic outlet by tumours or exostoses. 4. Progressive and perniciious anaemia. 5. Gravid chorea.

Relative Indications: 1. Great contractions of the pelvis with the conjugata vera below 8 cm. 2. Pulmonary embolism with signs of degeneration of the heart. 3. Nephritis, especially with oedema. 4. Chronic heart disease. 5. Other general diseases of the mother which jeopardize her life at the time of delivery.

...should not be ...
...N. T. Med. Soc.

Performance of the Cesarean Operation with Prolapse of the Placenta.

MASS has reported a case in which, following an abortion by means of catheter containing a stylet, the uterus was dilated and its contents removed with the aid of a catheter. It was found that the uterus was perforated, and through the opening a portion of lacerated small-intestine had passed the way. Celiotomy was performed, hemorrhage controlled, and the lacerations repaired, and the patient made a rapid and uninterrupted recovery. —*American Journal of Obstetrics.*

On the Line of Action to be adopted in the case of a Woman who is about to die whilst yet undelivered.

DR. REMMY says:—"Under circumstances such as these an effort must be made to save the life of the child, and, as a means accomplishing this, three plans have been suggested. They are—(1) To wait for the mother's death and then immediately to extract the child. (2) To do Cesarean section whilst the mother is yet alive. (3) To employ means to expedite labor and to extract the child by the natural passages as speedily as possible. REMMY then proceeds to discuss the relative advantages of these different modes of action. PRUSCHUBER's statistics show that when the mother is allowed to die before the child is extracted by abdominal section, only about 5 per cent. of the children survive. PUCH's statistics are somewhat more favorable; but there can be no doubt that the chance of obtaining a living child under these circumstances is very small. The performance of Cesarean section upon a dying woman, who is unable to give her consent to the operation, is undoubtedly open to sentimental objections. GUSEZNOV and MANASKE consider that the operation is justifiable under the following conditions:—(1) When it is clearly proved that the mother is about to die, and (2) that the child is alive. REMMY favors the plan of rapid dilatation of the cervical canal and extraction of the child *per vaginam*. Violent measures should be avoided, and the dilatation proceeded with as slowly as the condition of the mother will permit. The cervix may be dilated by means of Champetier de Ribes's bag, or by the hand alone. If traction is made upon the bag, dilatation may be produced in less than half an hour." —*Journ. de Med. de Paris.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

The Alkalinity of the Blood and Infection.

As the results of numerous experiments made on rabbits with a view to ascertain the influence of the alkalinity of the blood on diseases produced by the bacilli of anthrax, cholera, erysipelas, phthisis and typhoid, JOSEPH V. FUDON concludes:—(1) After infection with certain micro-organisms the alkalinity of the blood first increases and then more or less diminishes. (2) A distinct connection exists between the pathological condition of some bacilli and blood alkalinity. (3) It is not until after the diminution of the alkalinity to slightly acid conditions by an increase which becomes progressively higher that the infection; whereas in fatal cases the alkalinity is maintained and progressive. (4) The greater the alkalinity the more the resistance to infection. (5) The alkalinity of the blood and the power of the organism to increase the alkalinity of the blood are of essential importance in the outcome of infection.

The Role of Nervous Debility in the production of Fever.

STOCKHARD asserts that bodily or mental fatigue, indigestion, excitement pleasurable or of anger, or moral perturbation, which plays an established empirical role in the development of disease, may also retard recovery or aggravate such disease, but those factors that do not produce fever in a healthy person may and do produce fever in a sick person not directly by the perturbing influence but by the influence of the nervous system on the aggravated disease.

The Microbe of Scurvy.

TESTI and BERT have succeeded in isolating from a piece of scorbutic gum a micro-organism, which they believe to be the cause of scurvy. The microbe stain in all the aniline dyes resists Gram's stain, is perfectly round, and generally united with one or more of its kind. Its culture renders gelatine fluid, and gives rise to a sawdust-like deposit. Inoculation of these cultures into guinea-pigs and rabbits gave rise to fever, and the necropsy showed hemorrhagic stains in various parts of the body, and nodules of connective tissue new formation. Experiments were made in four cases, and in three out of the four the above-mentioned results were obtained; in the fourth case the authors attribute their negative results to the fact that the patient had improved considerably under treatment. The diplococci found by the authors differ considerably from any that are usually present in the oral cavity of man.—*Brit. Med. Jour.*

The action of Light on Bacteria

THOUGH not quite prepared to declare conclusively for all varieties of bacteria, Professor M. WARD corroborates the wisdom of the ancients as to the hygienic value of sunlight, for when he interposed a screen of potassium bichromate solution between bacteria and sunlight and thus cut off the blue ray of the spectrum, the microbes flourished as freely as they would in the dark. Similar results obtained with red, orange, yellow and ultra violet light; but violet light killed or injured a large number of the colonies, while blue rays of light or direct sunlight instantly destroyed the bacteria.

New Method for Detecting Tubercle Bacilli in Sputum.

IRKEWITSON claims the following to be the quickest and surest mode of diagnosing phthisis when the clinical signs are scanty:—8 minims of the sputum with 300 of water and 8 drops of 30 p. c. liquor potassæ are stirred together in a porcelain capsule and then heated till vapor forms, a little casein is now stirred in, 2 or 3 drops more of liquor potassæ added and the whole heated till the translucent fluid becomes milky in color, when it is transferred to a glass test tube and acetic acid added, drop by drop, till the albumen just begins to clot and the whole mixture is then churned for 5 or 10 minutes in a centrifugal brass cylinder. A deposit forms, carrying with it all the bacilli present. This is collected, rubbed between 2 slides, dried, fixed in the flame, stained after ZIEHL's method and examined under an oil-immersion lens for the presence of tubercle bacilli.

Variable forms of Bacteria.

THE theory advanced in 1889 by R. S. CHW of the possibility of errors being made in diagnosis owing to bacilli changing their appearance according to their nutrient media and their inherent qualities was received with mountains of ridicule; but E. KLICK, one of the most eminent of bacteriologists, now affirms that though like produces like bacilli not only take their own time and require suitable conditions to reappear in any one of a cycle of protean forms, but also present varieties in shape dependent on the medium in which they

grow and also on certain inherent qualities of themselves. His conclusions are based on observations of almost every known form of specific or pathogenic micro-organisms, and he further declares that under many conditions they have morphological characters of typical bacilli, but under other conditions they easily revert to or assume forms which, though trending often to misleading diagnoses, yet show their evident relation to the saccharomycos or other mycoid fungi.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Death in Bank-Notes.

ACCORDING to *L'Independence Belge* the cashier of a Viennese bank met with his death a short time ago under circumstances as remarkable as they are happily rare. Having to count a large number of used bank-notes, all more or less soiled and difficult to separate from each other, he incautiously, and in spite of a friendly warning regarding the risk he was thereby encountering, endeavoured to facilitate his work by moistening his fingers and thumb with his saliva. The same evening he felt a tingling pain in his lips, but did not pay much attention to this symptom, thinking it would pass away. The next morning, however, his mouth and tongue were hot and swollen, he began to feel alarmed, and without loss of time consulted a medical man, who is said to have forthwith incised the tumour. What the effects, immediate and remote, of this procedure were we are not told, the remainder of the history being briefly summed up in the following terms: "Notwithstanding the operation the patient died three days subsequently from the effects of the poison which he had absorbed." There are some points in this case, as set forth by our lay contemporary, which require elucidation. It is to be hoped, therefore, that an account from a qualified source will be forthcoming.

Wrapping Paper for Articles of Food.

THE city of Montpellier is said to be the first in France to adopt regulations concerning the kind of paper to be used for wrapping up articles of food. By a municipal decree, in force for some months, the use of colored paper is absolutely forbidden. Printed paper and old manuscripts may only be used for dried vegetables, roots and tubers. For other articles of food, new paper, either white or straw-colored, must be used.

The Alum Process of Sterilizing Water.

ACCORDING to Teich almost always diminishes the number of germs. Yet this is only temporary, for an increase soon results. Typhoid bacteria are not harmed by the process, which must not be relied upon to effect their certain removal from the water. Although alum can destroy cholera bacilli in time, the process is a slow one, lasting more than a day. Hence this (Baker) process is practically worthless.

Disinfection of Wells.

DR. FRANCK has brought under the notice of the Polytechnic Society of Berlin a means of disinfecting wells which he employs with success. It consists in suspending in the mouth of the well an earthenware dish containing 50 to 100 grammes (a gramme is about 15 grains) of bromine, which, being volatile in air, forms a dense vapour that fills the well and is absorbed by the water thus disinfecting it. The water has a slight taste of bromine for a time, but is wholesome.

Necessity of Frequent Visits.

THE Supreme Court of California (*Tobbs v. Myers*, 40 Cal. 355), in an action brought by a physician for professional services—the defence being that the visits were too frequent and not necessary—ruled that:

The writer has observed numerous instances of the physician who, in the effort to cure the patient, has placed the patient in a position of danger, and in the attempt to cure the patient has caused the patient to die. The writer has observed numerous instances of the physician who, in the effort to cure the patient, has placed the patient in a position of danger, and in the attempt to cure the patient has caused the patient to die.

It would seem, however, that the doctor to require a physician to be able to prove the necessity of each visit before he can receive his services. This is necessarily a matter of judgment, and one concerning which no one says the attending physician can decide. It depends not only upon the condition of the patient, but in some degree upon the course of treatment adopted.—*The Sanitarian*.

Penalty for Circulating False Reports.

THERE is a law in Florida which provides that "any person or persons who shall falsely or maliciously disseminate or spread rumors or reports concerning the existence of any infectious or contagious disease shall be guilty of a misdemeanor, and, upon conviction, shall be punished by a fine in a sum of not less than \$100 nor more than \$1,000, or be imprisoned in the county jail for not less than three nor more than six months."

A Question of Responsibility.

Two men were suffocated in a cistern at Bristol last week under very unusual circumstances. Some defective drains were found in the house of a dental surgeon, and when the drain was opened, it was discovered that a rain-water pipe led directly into a cistern. The cistern was on the cellarage floor, and access was obtained to it by means of a man-hole. A pipe also led from a photographer's into the tank, and the chemicals used by him in his work would drain into it. It was advised to clean out the cistern and fill it up with rubble, so as to get rid of any nuisance, as well as the cistern itself. The contents of the tank were pumped out to about twelve inches from the bottom; this sediment the unfortunate men tried to remove, but they were quickly overcome by the sulphuretted hydrogen gas which was liberated by the disturbance of this sediment. They both expired before any assistance could be given them. This gas was the product of special chemical action by the percolation into the tank of the waste preparations used in the process of photography. At the inquest the coroner stated that there was no criminal negligence of any sort. Certainly the case is most exceptional, and the question of responsibility is practically incapable of solution.—*Lancet*.

—10—

THERAPEUTICS AND PHARMACOLOGY.

Action of Antipyretics on the Blood.

HERSCOVITZ points out that one of the antipyretics most in use, namely, antipyrin, has a powerful haemostatic action. This property he claims to have discovered in 1884, in the course of some experiments with this drug. The haemostatic action is local and its mechanism is vaso-constriction and retraction of the tissues, with formation of a minute clot which is extremely retractile and aseptic. Antipyrin has also a favorable effect on coagulation. The action of antipyrin on the blood, when administered in toxic doses, may be summed up as a transformation of oxyhaemoglobin into methaemoglobin. A phase of anaemia or diminution of oxyhaemoglobin precedes the accumulation of methaemoglobin. In this period there is at the same time production and elimination of methaemoglobin; if elimination is hindered, as transformation is too rapid, phenomena of cyanosis may be produced which must be distinguished from those of the period of intoxication. These various phenomena may be studied haematoscopically, and the influence of antipyrin on

the blood may be observed by the use of the microscope. The writer has observed numerous instances of the physician who, in the effort to cure the patient, has placed the patient in a position of danger, and in the attempt to cure the patient has caused the patient to die.

Ready Method of Removing Foreign Bodies from the Throat.

THE following is a description of the method as practiced at the Göttingen clinic: The operator, standing on the left of the patient and facing him, places the ball of the thumb of the opened right hand upon the patient's throat between the place of the larynx and the sternum. He then repeatedly presses in the throat with a quick strong movement, at the rate of about one hundred times per minute. The results by this method have been very satisfactory.

Belladonna in Catarrh Caused by Potassium Iodide.

GEORGE COHEN, of Hull, has been able in three cases to stop the catarrh following the use of 10 grains (0.66 grammes) of iodide of potassium in 1 ounce (16 grammes) of water, by adding to this mixture 5 minims (0.32 grammes) of tincture of belladonna per dose in order to reduce the salivary secretion. It also counteracts the so-called depressant action of the potassium.—*Lancet*.

Varicose Veins treated with Ergot.

J. FERRIS reports two cases cured with fluid extract of ergot. One, a very bad case, but frequent hemorrhages, was cured in three months, without bandaging or any local application. He remarks that if the coatings of the blood vessels were strong enough to resist the blood-pressure there would be no varix; and to what extent the dilatation is compensatory is unknown. It is possible that the drug is so far reaching in its action, that it overcomes the cause as well as causes tonic contraction, thereby giving nature a chance to heal and strengthen the weakened parts.—*Amer. Med. Surg. Bull.*

Ichthylol to Abort Furuncles.

According to DR. CANTRELL, a 50 per cent. ointment of ichthylol applied thoroughly over the irritated part will usually abort a furuncle in about twenty-four hours.

Mixture for "Sluggish Liver and Indigestion."

R. Acid. Nitro-hydrochlor. (dil.) ℥ss.
Tinct. Podophyllin ℥ss.
Succ. Taraxaci ʒj.
Tinct. Nervi Vom. ℥ss.
Syrup Zingiberis ʒss.
Aq. Menth. Pip. ad ʒss.

S.—In water three times a day.

Cannabis for Itching.

MACKENZIE has found that Indian-hemp gives relief in cases of skin diseases, where the itching was not amenable to local means. The full effect must be produced promptly. For this purpose he employs the tincture in doses of ten drops, on sugar, repeated as often as necessary.—*Phil. Mag.*

Angina.

For simple angina Dr. Pepper prescribes—

R. Potass. citrat. ...
Potas. bicarb. ...
Ext. belladonna ...
Syr. marshm. ...
Aq. ...
M. Sig.: Take one or two drachms three or four times a day.

entrusting custody of the Honorable East India Company the British Government never engaged itself to do the Indian Government down to the 18th bits the H. E. I. Company used as bait to secure its men.

(2). Every private soldier carries a Marshal's baton in his keespake; but how many really smart Surgeons-Lieutenants or Assistant Surgeons may rise to Deputy Surgeon-General, for instance, except by seniority?

(3). As the Indian Medical Service was not created till long after the formation of the Hon'ble East India Company in A.D. 1700 while LANGDON, SETON and MOORE, three Civil (i.e., private) medical practitioners (adventurers if you like to call them so) who came to India as doctors to merchant-ships, not belonging to H. E. I. C., were appointed State-physicians to H.R.H. Prince Akbar, the Great (A.D. 1603) I fail to see how the service doctors were first in the field.

(4). *Otes toi que je m'y mette* cuts two ways, and though the Indian Government mother may tell her civil practitioner son "TOMMY make room for your UNCLE the service doctor," still the uncle has no right to live *sans souci* at TOMMY's expense on conditions not quite *sans peur et sans reproche* and as *defendant* TOMMY is perfectly justified in rejecting the *sauve qui peut* the UNCLE hurls at him for refusing to vacate his chair in favor of the UNCLE who is already occupying two more than he can properly fill or stretch himself to sit upon.

(4). There is no wisdom in telling a man what he already knows but does not find convenient to recollect even when his memory is jogged.

(5). When ALEXANDER the Great invaded India, he found it highly civilised (Before CHRIST). So also at the time of the Mogul and Mahomedan conquests and long before CLIVE was even dreamed of VASCO DA GAMA (A.D. 1428) landed at Calicut and wrote of India. "I have discovered a rich land of great culture and exceeding high civilisation." I think this disposes effectually of the vain boast of the British civilising India.

(6). If a man holding army rank ceases to be military because, co-existent with his army title, he is loaned to civil employ *all* he be recalled to military duty does a cavalry soldier become an infantryman or a civilian when his horse dies and he is obliged to fight on foot or wait for another animal from the remount stud?

(7). Will Surgeon-Lieutenant-Colonel C. H. JOUBERT kindly inform the profession how many I. M. S. officers are on the professor staff of:—The Calcutta Medical School, the City School of Medicine, the Vernacular Medical College, the Campbell School (excluding the Police Surgeon) and the Calcutta College of Physicians and Surgeons? All in this city.—NONE.

I have not anywhere denied the value of the services rendered to India by I. M. S. men such as COATES, MCCONNELL, RAY, PARTRIDGE, CUNNINGHAM, C. H. WOOD, MCKENZIE, McLEOD, KING, HARVEY, WARDEN, CHANDRA and LAWRIE, whose memories I appreciate and reverence as leading lights; but I do maintain that India has reached that stage of medical education and perfection which renders her quite capable of putting forward scientific men without indenting on the Indian Medical Service for teachers, and there is no reason why the plums in the giving of Government should continue to be reserved for the Indian Medical Service while the actual work devolves on the subordinate establishments.

Mr. FRANK HART did not show at the I. M. S. before the lay public. He made a cutting expert before the British Medical Association (not a lay society) and the journal of that Association (i.e., the *B.M.J.*) published Mr. HART's speech which the *Englishman* (a lay journal) reproduced, whereupon Mr. C. H. JOUBERT M.B., F.R.S., constituting himself champion for the entire I. M. S., writes a long letter to the *Englishman* in which ignoring the claims of the civil practitioners, he pitches into Mr. HART for daring to find fault with the errors of officialism, pokes fun at the poor old man, tells us he is himself some 32 years connected with medicine, and concludes by notifying to the general public that besides being a Surgeon-Lieutenant-Colonel of the I. M. S. he holds the much coveted and most thought of diploma of M.B. of London, and is a Fellow of the Royal College of Surgeons of England.

I certainly do not plead guilty to the charge of "repudiating the I. M. S. men as professional confrères," and though in upholding the principle of maintaining the prestige of the civil practitioner I decline to meet or call in the service men in bed-side consolation, still I entertain a very high opinion of the mental calibre and scientific attainments of very many of them, and candidly admit that those of them that I have had the pleasure of measuring lances with in medico-legal trials, were (though I won) worthy foes who tried my utmost skill and gained my admiration; but, for all that, honor compels me to stand by the church militant and battle with my pen and example until the civil practitioner obtains the privileges he has fully earned by passing his examinations and paying heavy fees for tuition in India.

So if, in fighting this terrible fight for existence and striving for recognition of the hard-earned rights of my class, I do happen to mention a few home truths, however unpalatable, about the monopoly by the I. M. S., I trust my service UNCLE, Surgeon-Lieutenant-Colonel C. H. JOUBERT, will not construe a public grievance into personality to himself; but that rising to his better nature he will try to help instead of crush his nephew.

CIVIL MEDICAL PRACTITIONER.

10th October 1895.

THE MEDICAL PRACTICE QUESTION IN INDIA.

TO THE EDITOR, "THE INDIAN PLANTERS' GAZETTE."

DEAR SIR,—As you are taking up in the *J. P. G.* the subject of the iniquitous competition of officers of the I. M. S. with private non-official doctors in the matter of practice, perhaps a few facts will be of use to you.

1. The present I. M. S. is the successor of the same service under the East India Company. The privilege of private practice, was assured to the Company's Medical Officers by Act of Parliament. It was this privilege which induced good men to accept the Company's service on the small pay offered. Medical officers who joined Government service since John Company became extinct and who now join had had to agree to accept any rules or changes the Secretary of State may choose to make. The rates of pay have remained the same or

been decreased, in any notion of the fall in value of the service. The Secretary of State has thought it advisable to withdraw the privilege of private practice from the service in general, though departmentally many restrictions have been placed on it with respect to numerous particular appointments.

It is an undoubted fact that most young doctors enter the I. M. S. with a view to civil employment and the private practice allowed. There are prize appointments in the service, which offer rather a fine career and good financial prospects from private practice. The London examinations always shew the Indian candidates to be superior to those who compete for appointments in the Army Medical Staff (British service). Were the privilege to be withdrawn only the most inferior men from medical schools would compete for service with native troops or civil appointments not carrying private practice.

2. "The I.M.S. at present consists of over 650 officers, of whom over 340 are in civil employ. The prize appointments are not numerous in proportion to these large numbers. All medical officers have to be content to work for years in small appointments, in small civil stations, where they get little more than their bare pay and have very hard work. Many never get beyond this stage, but have to content themselves with hope for the future. Where are the non-officials who would be content to establish themselves for life at Jessore or Rungpore or Burdwan or Berhampore? And what would they do when ill health, or wearing called for a change to Europe?

"In point of fact the outcry of the non-official against the official doctor applies only to the presidency towns and the coveted hill-stations. They want the kernels and are quite content to leave the husks to us.

Take then the presidency towns. Calcutta for instance. The hospitals, to which the non-official doctors claim to be appointed. These are all Government institutions, not private ones as in England. The charge of them forms only part of the duties of the official doctors, and Government has surely a right to select from its large service of 650 tried and experienced medical officers for these posts men who have proved themselves to be good and competent doctors. The alternative would be a choice from amongst perhaps half a dozen leading non-official practising doctors in Calcutta, for surely the lower grade of general practitioners would not consider themselves eligible out here any more than the ordinary general practitioners would at home. A London hospital surgeon or physician is always a man of high profession either *in esse* or *in posse*. But say Dr. B. or Dr. C. or Dr. G., non-official, is appointed to one of the Calcutta hospitals, and after a few years' work wants a year's furlough. Who is to replace him? The few eligible non-officials would hardly suffice for one of the large Calcutta hospitals.

"Private Practice.—There are at present 30 officers of the I. M. S. holding various civil appointments in Calcutta, and of these eight only have the privilege of private practice. Of the twenty-two debarred from practice, one only has the privilege of consulting practice. The eight others are to take fees from the public for other than their Government work, besides their hospital duties, have to

attend gratuitously all Government Civil Servants drawing more than Rs. 300 monthly, whether stationed in Calcutta or merely temporary in Calcutta, all Military Officers and their families living outside Fort William, all Chaplains and their families: they have to examine all candidates for Government service, all Government servants requiring sick certificates or applying for pension, all candidates for Government Post Office insurance.

"They are all senior men of large Indian experience, they are men who have come to the front rank of their service for special proficiency and attainments in particular lines of their profession or in special branches, they are the picked men of a picked service, and when they retire or go on furlough, Government has many other to replace them, as good or better than they. Is it wonderful therefore that the public has confidence still in these men, like to employ them as their family doctors, that insurance companies prefer to make use of their mature Indian experience to that of the new arrival in India, a young man perhaps who has been brought out as assistant or partner to an overworked non-official doctor, who wants a run home and has no one to leave in charge of his practice? Is it wonderful that banks, mills, firms, schools, public bodies generally still think that these selected eight senior men with their long years of Indian experience and the prudence acquired by official training are as good as or, possibly, better than the non-official doctor, who comes nobody knows from where or with what experience of India, and who may be here to-day and away to-morrow, whereas, as I have said, if the official practising doctor goes away, his patient feels sure that his successor will be as good a man or, if not, better than he. There is a certain sure continuity in one case and a total absence of certainty in the other.

"The cry against the official doctors in practice comes from the lower ranks of the non-official doctors from men who would be in the lower ranks in England, and none of the half dozen superior non-official doctors in Calcutta can say that they have not been treated with courtesy, generosity and total absence of jealousy by the practising official doctors in Calcutta. There is plenty of room and plenty of work for them, but when it comes to giving up our plums to them because they cry for them—plums that it has taken us 15 or 20 years to work up to in small ill-paid appointments—human nature steps in and we say no; as long as Government is satisfied that we don't neglect our official duties in the scramble for the wily rupee, and as long as the public chooses to honor us with their support and patronage, what we hold we will stick to and try to pass on to our successors, who are now toiling away in wretched mofussil stations in hopes of some day stepping into our coveted shoes." Yours, &c., ABDI ALTERAM PARTEN.

[Our correspondent's argument are based chiefly upon service traditions. He finds it necessary to go back to the days of Old John Company, to justify this objectionable system of monopoly. He falls back on the old traditional notion that the Service is one of "picked men," and from this "picked" assembly, "special picks" are made for the Service "plums." No one outside the Service could possibly do the work done by the Service. We have felt very strongly about this monopoly question for years, and we can assure our readers that our correspondent is absolutely in the dark when he says the

agitation. The Public Health Board has "taken the matter into consideration." We know for a fact that the whole non-official profession is deeply grieved, for matter of that, in India, is in sympathy with our views on this subject, and the feeling for reform on the lines we have indicated is universal. Our correspondent is unfair to those private practitioners who have by their pluck and hard study made names for themselves and gained a very firm and popular footing not only in Calcutta, but in Madras and Bombay.

In our remarks we protest against being misunderstood. We are directing our energies against a system of medical abuses that amounts to a public scandal. We have no desire to enter into personalities, and we will not do so. If we are compelled to isolate an office or special appointment, to give definiteness and point to our remarks by way of an example, we trust we shall not be misunderstood and our meaning misconstrued into personalities. Scores of extra copies of our journal containing our article on "The Medical Practice Question in India" have been bought by doctors throughout Bengal and Assam, with the object of sending them home to friends and members of Parliament, and this fact alone bespeaks a deep and general interest in this very important public question.—Ed., I. P. G.]

THE ILL-PAID HOSPITAL ASSISTANTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—It does at first sight seem surprising, and is to be regretted that up to now only 40 or 50, of the Civil and Military Hospital Assistants have joined the Indian Medical Association whereas some hundreds ought to have swelled the rolls. But what can be done?—charity begins at home, and the mind is willing enough but the purse is too tight. Stomach must take the front rank, while philanthropy brings up the rear.

For some time past I had been putting domestic economy to a severe test, so as to spare the small subscription necessary to enable me to join the Association, but month after month there was the same "deficit in my household budget" and I could not make both ends meet.—Of course dreaming of the "Hospital Assistant's Memorial" for the little would-be-increment of pay and pension is hoping against hope.

However it is true that all of us Hospital Assistants made a special effort to immediately join the Association, even at the sacrifice of a few necessities of life that we may try to do without—we possess no luxuries.

Yours, &c., M. A. A.

SIR,

INFORMATION WANTED.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I shall be extremely thankful to know whether Surgeon-Captain ROBERT HENRY ELLIOTT, M.B., B.S., London F.R.C.S. England & F.R.C.S. Cambridge, &c., I.M.S., acting Professor of Biology, Presidency College, Madras, is the same as or is identical with the Surgeon-Captain Elliott who is now appointed Ophthalmic Physician, Surgeon, and Oculist at the Presidency of Madras, and his whose hands so many millions of eyes are entrusted.

Yours, &c., JOHN ANDERSON.

GOVERNMENT OF INDIA.

Surg. Capt. U. R. James, I. M. S., is placed at the disposal of the Punjab Govt. from 30th July 1895.
Vet. Lieut. E. W. Lardner, C.V.D., is transferred to Punjab from 15th Sept. 1895.
First class Mty. Asst. Surg. George Gill is granted 600 days' furlough from 18th Oct. 1895.

PROMOTIONS.

To be Sarg. Lieut. Col.—J. W. Clarkson and J. Parker, M.D., from 30th Sept. 1895.
To be Sarg. Maj.—G. J. Barkin, M.B., from 30th Sept. 1895.

BENGAL GOVERNMENT.

Leave has been sanctioned as under:—

Brig.-Surg. Lieut. Col. C. J. W. Meadows, 6 months' special leave. Sarg. Lieut. Col. J. O'Brien for 6 weeks from 23rd Sept. 1895 and C. H. Jonkers for 40 days from 6th Oct. 1895. Sarg. Capt. J. R. Adie six months' extension of leave w.o. without pay. Asst. Sarg. Pransha Nath Banerjee for 1 month and 15 days and Chander Mohan Ghose for 3 months.

H. I. and R. H. the Queen has ordered the following gentlemen to be admitted to the I. M. S. as Sarg. Lieut. from 29th July 1895:—John Stephenson, Frank Needham Windham, Walter Barrie Turnbull, Ernest Edwin Waters, Asher Lavanton, Philip Francis Chapman.

The following appointments are ordered:—Surg. Maj. A. Tomes to act as Prof. of Surgery, Med. Coll., Cal. Surg. Capt. B. Bird to act as Prof. of Anatomy Med. Coll. Cal., F. J. Drury to act as Prof. of Midwifery Med. Coll., Cal. Asst. Surg. Preumber Mitter to Pres. Genl. Hosp. Calcutta; D. N. Mitter to act as Teacher of Anatomy to the Campbell Med. School; Behari Lal Chakravarti to act as Rees. Surg. Med. Coll. Hosp.

PUNJAB GOVERNMENT.

Privilege leave is sanctioned as under:—

Surg. Maj. G. W. P. Dennis for 2 months from 5th Sept. Surg. Capt. R. B. C. Barber for 16 days from 3rd Sept. First class Hosp. Asst. Paramasand, 6 months from 31st Aug. 1895. Second class Hosp. Asst. Hira Singh, 3 months from 16th Sept. 1895; Muhammad Aslam, 3 months from 14th Sept. 1895; Rakh Ram 20 days from 31st Sept. 1895. Third class Hosp. Asst. Ameer Khan is entitled to the higher pay of his grade from 8th Sept. 1895.

The following appointments are made:—

Surg. Maj. O. H. James to be placed at the disposal of the Punjab Govt. from 29th July 1895; Vet. Lieut. E. W. Lardner, C.V.D., is transferred from Bombay to the Punjab command; Dr. D. N. P. Dutta to off. as Civil Surg. and Supdt. Lunatic Asylum, Delhi, from 5th Sept. 95 etc. Surg. Maj. G. W. P. Dennis on leave. Asst. Sarg. Khuran Chand, off. Civil Surg. Bikaner, from 2nd Sept. 1895; Babu Ditta for genl. duty Amritsar from 22nd Sept. 1895; Balu Singh, Gujranwala Dist., from 15th Sept. 1895; Bishen Das to Lalay Nana Hosp. N. W. Ry. from 15th Sept. 1895; Sodhi Karm Singh to genl. duty Amritsar, from 15th Sept. 1895; Lachman Das to the Mayo Hosp., Lahore, from 20th Sept. 1895. First class Hosp. Asst. Masadi Mal to genl. duty at Rawal Pindi from 30th Sept. 1895; Second class Hosp. Asst. Humaid Bakshi to Miani Dargy, Multan Dist., on 2nd Sept. 95; Third class Hosp. Asst. Abdul Samad to N. W. Ry. Hosp. on 1st Sept. 1895; Ramjan Bat for genl. duty at Multan from 2nd Sept. 1895; Asst. Singh for genl. duty at Multan from 11th Sept. 1895; Mohi Ram for genl. duty at Jalandhar from 2nd Sept. 1895; Ghansh Das to Ludhiana Travelling Disp. from 15th Sept. 1895; Karam Singh to Gujranwala City Hosp. from 15th Sept. 1895; Abdul Rahmand Khan to the N. W. Ry. Branch Disp. Faisalwar from 27th Sept. 1895.

Medical charges were assumed as under:

Surg. Maj.—C. J. Barkin, of Punjab, from 30th Sept. 1895. Surg. Capt. J. W. Clarkson, of Punjab, from 30th Sept. 1895. Surg. Lieut. Col. J. O'Brien, of Punjab, from 30th Sept. 1895. Surg. Capt. J. R. Adie, of Punjab, from 30th Sept. 1895. Surg. Lieut. Col. C. H. Jonkers, of Punjab, from 30th Sept. 1895. Surg. Capt. J. W. Lardner, of Punjab, from 30th Sept. 1895. Surg. Lieut. Col. J. O'Brien, of Punjab, from 30th Sept. 1895. Surg. Capt. J. R. Adie, of Punjab, from 30th Sept. 1895. Surg. Lieut. Col. C. H. Jonkers, of Punjab, from 30th Sept. 1895.

100

Wesleyan University

Sir,—In reply to your letter of the 15th inst., I have to inform you that you will be required in order to obtain the L. E. C. P., or the R. O. S. to pass the second examination in Anatomy and Physiology as well as the final exam. in Med. Surg. and Med. Geo.

4. Of having obtained the Licence in Medicine and Surgery of the Bo. University.

I am, Sir, &c.
FREDERIC G. HAMLET,
Secretary.

PERSONAL HYGIENE.

DR. S. J. MÜLLERS, D.M.S.

Brissellique.

Continued from page 315, Vol. IX.

WATER is needful for every animal and vegetable, and without it both would die. The greater part of our bodies consists of water. If a man weighs 150 lbs., the water amounts to about 112 lbs. When we eat, our food first becomes like a pulp in the stomach. The useful part, chyle, somewhat like milk, is changed into blood, while the waste part is sent out. The blood goes through little pipes to all parts of the body for their nourishment. If there was not enough water, the blood would be so thick that it could not flow through these little pipes, many of which are far finer than a hair. The water we drink passes into the blood and then goes to every part of the body. If the water is bad, our health must suffer. Water is also useful for cleansing our bodies. This takes place not only when we are washing ourselves with it, but by day and night it is slowly pouring out in the form of perspiration through millions of little drains in the skin.

Sources of water supply.—(1) *Rain* is the greatest supplier of water. The heat of the sun causes water to rise in vapour which is changed into dew, rain or snow. Rain, as it falls, is nearly pure but becomes impure by coming in contact with the roofs of houses, whence it washes down dust, dung of birds, bones, &c. When the rain runs along the ground it gathers mud and decaying matter.

(2). *Rivers* usually contain good water, but during the rains, they are muddy. This water, however, clears when allowed to stand for some time, or it may be quickly purified by the addition of a little *alum* or the well-known clearing-nut, *strychnos potatorum*, (Tamil *thakankotai*.) Washing clothes or cattle in rivers tends to pollute them. People often use the banks of rivers as latrines, and the rain washes the filth into the stream. Dead bodies (even of people who die of cholera or small-pox) are sometimes thrown into rivers which also receive the ashes of crematories. Thus rivers, the sacred streams not excluded, are frequently used as places into which filth of any kind may be thrown; but the harm is much greater when (as is often the case) there is only a very small stream with scarcely any flow.

(3). *Lakes* contain excellent water; but water from a lake in a *marsh* or *jungle*, even though it may look pure, generally contains decaying vegetable matter, which is apt to cause malaria.

(4). *Tanks* are a fertile source of trouble, as they contain standing water which is easily polluted. People bathe in them, rinse their mouths and spit into them, wash their clothes and cooking pots in them, and cleanse themselves in them after using the bank as a latrine; cattle and swine lie in them; and plants are frequently steeped in them. Yet water is taken from them for drinking and cooking.

(5). *Wells* supplied by water very deep in the soil, are good; but those depending upon water near the

surface are wholly bad. The ground is often full of filth, which has been gathering for ages, and water passing through it is polluted. A common fault with water wells is, that they are devoid of protecting walls, and water charged with all sorts of abominations is allowed to run back into them to pollute the whole supply.

Hurtful effects of bad water.—Of all diseases *fever* kills the most people, and its most frequent cause is decaying matter in water. Statistics show that bowel complaints produced by unwholesome food and bad water carried off nearly three lakhs of persons in 1865. Deadly outbreaks of disease have been traced to polluted matter from a cesspit draining into a well. Cholera is still a pestilence, but its ravages have greatly diminished in those towns whose water supplies are looked after. The Madras Sanitary Commissioner says in one of his reports: "An improved water supply is the greatest sanitary need of our Indian municipal towns. Until the frightful water contamination, which at present prevails is overcome, all our other efforts are almost nugatory."

How to get pure water.—Impurity is to a certain extent inevitable, and is neither disagreeable to the taste nor injurious to the health. Though a good water is not necessarily chemically pure, it is one which is transparent, colorless, odorless and tasteless, and holds a sufficient amount of atmospheric air, in solution, but does not contain suspended matters, or excess of total solids or of any particular substance dissolved in it. Sometimes a water will look clear and bright and be impure. A well in London, noted for its bright, sparkling water, was near a graveyard, and when examined, was found to be very unwholesome. Water is called "*hard*" when it contains too much lime or other mineral matter; and "*soft*" when the minerals are small in quantity or absent. Soft water is best for cooking and washing, and there will be a saving of firewood and soap, besides time. The large towns of England have pure water running through the streets in pipes. A few towns in India also are thus provided with water at present, and in course of time others will be supplied.

River water from large streams is generally the best, as it usually purifies itself by being turned over and over and being freely exposed to the air. The quality of *tank* water, which is rain water, filtered through the soil, depends upon the position and the care taken. The water of tanks which dry up or get very low in the hot season is unwholesome. Fish and living plants in tanks do good, but dead leaves and decayed plants are hurtful, and no sort of filth should be allowed anywhere near a tank lest it be washed into it by rain or soak into it through the ground. Tanks set apart for drinking water should be watched to prevent their being polluted. Another large tank should be reserved for bathing, washing, and watering cattle; but even here care should be exercised, as clothes washed in dirty water do harm, and good water is just as necessary for beasts as for man. Many of the diseases cattle suffer from (such as worms) are really due to bad water. Wells should be surrounded by a wall that slopes outwards, so that any water spilled on it may run off; and bathing

* For a fuller account of these matters the reader's hand-book of water analysis and purification, obtainable at this office.—E. M. S.

or washing should not be allowed near wells, nor should trees overhanging them, as leaves may fall into the water and decay. A cover would be a great protection to a well, and clean vessels and ropes should always be used in drawing water. Now and then wells should be cleaned out and any broken pots or fish that have fallen into them carefully removed.

Campfires should not be permitted near a well, and the proximity of filth is very harmful, as water absorbs bad odors. The vessels in which water is kept or drawn should be scrupulously cleaned every day. Any person who has had small-pox or other infectious disease should not be allowed to wash himself, nor his clothes in any tank, or near any well, used for any domestic purposes. Wells sunk in granite yield pure water, but the neighbourhood of burial grounds, cesspools, sewers or ill-constructed surface-drains, nullahs (invariably used as latrines), tanneries and slaughter-houses, unclean dwellings, stagnant surface-pools or tanks in which people or animals bathe or clothes are washed, fields which are freely manured, should be avoided in choosing a well for domestic use.

Purification of water.—Pure water should be obtained, if possible, and kept pure after being well boiled, as boiling destroys any live poison capable of creating disease. This is especially necessary when fever or cholera is prevalent. Filters, if properly made and kept clean, are useful, but if dirty they add to the impurity of the water. Common filters are formed of three earthen pots, one above the other, each covered with a perforated earthen lid and supported by a tripod of wood or iron. The two upper pots, provided with small holes in their bottoms, loosely plugged with cotton banting or a straw, are half filled with a mixture of clean sand and charcoal, the lowest of the three receives the filtered water. The sand and charcoal should be frequently replaced by fresh clean materials and the pots cleaned out. If fresh sand and charcoal cannot readily be obtained, they can be rendered fit for use again by being thoroughly heated. The earthen lids should always be kept on to prevent flies and dust from getting in.

WHAT IS REMITTENT FEVER? *

By N. N. KATRAK, L.M.S.,
Bombay.

In the Mortuary Returns of the Health Officer for the city of Bombay for the year 1893-94, it is stated there that 21 deaths are due to enteric fever, 831 to simple continued fever, 262 to ague, and 4,730 to remittent fever. The question arises what is meant by remittent fever. It is well-known that intermittent fever becomes exaggerated and intermissions are converted into remissions, but these cases yielded to quinine as readily as the ague; besides during the remission, though the temperature does not go down to the normal, still there is a considerable descent from the highest point reached, and symptoms are abated during that period; but such cases are few and far between. The bulk of them does not yield to quinine, nor do the symptoms abate during remission. It is a misnomer to call the little dip in the temperature

which we find in these cases a remission. There are slight variations and trifling intermissions, but it is not a continued fever, hence they cannot be of the nature of ague, i.e., amenable to quinine, and constituting the same bodies (LAFERAN'S). That these cases were hitherto, and even now are by some, regarded as due to the same poison as that of the ague is evident from the fact that large and even heroic doses of quinine were, and in some cases even now are, administered in such cases; but this practice is becoming less frequent every day. Again, those cases of remittent fever, which do not yield to quinine, are by some regarded as cases of typhoid fever, as will be seen from the following para. quoted from SIR WILLIAM MOORE'S "Diseases of India," second edition, page 285:—

"Deputy-Surgeon-General Pinkerton, several years the able Surgeon to the European General Hospital, Bombay, states he is quite sure that what we now call the enteric fever has existed over 50 years in Bombay, and has been known as 'the 21 days bad Bombay fever'. The same authority informs me of his opinion that the disease is in every respect as in Europe, and that it has no connection with malarial fever, taking ague as the type; also that enteric fever exists all over Western India, killing an enormous number of natives under the name (in the Mortuary Returns) of remittent fever or simple fever. With Dr. PINKERTON'S views as to the indefinite existence of enteric fever in Bombay, as to its being the same phase of disease as seen in Europe, and as to its causing great mortality among the natives I fully agree; but I believe it to be simply a phase of fever and not a specific disease of pythogenic or miasmatic origin.

This opinion, however, does not seem to have received universal acceptance, as in the Sanitary Commissioner's Report the bulk of cases are still included under the heading of remittent fever. Even among European troops the admissions for enteric fever were only 1,362, as against 22,749 for remittent. Among the native troops only 33 admissions are put down for enteric fever, as against 54,347 for remittent fever. Again, in well-conducted hospitals, such as the Goculdass and the J. J. Hospitals, the proportion of typhoid fever to remittent fever is extremely small. In the Goculdass Tejpaui Hospital from 1888 to 1892, no admission has been recorded under the head of enteric fever; whereas for the same period the admissions into the J. J. Hospital are 17 cases of typhoid fever, as against 2,526 of malarial. I believe that it might be safely said that the bulk of the remittent fever cases cannot be and are not regarded as cases of typhoid fever in accordance with the views of Surgeon-General PINKERTON and Sir WILLIAM MOORE. Then the question still remains What is remittent fever? It is by some regarded as modified typhoid; but to say the least, the term is very vague. It is not quite clear what the term modified typhoid fever means. It may mean that the germ is the same germ, namely, Eberth's, but it does not produce the same symptoms as are found in the true enteric. But the presence of this germ in cases of remittent fever has not yet been established, and it is not quite clear in what way the system has been modified to produce different symptoms, and it is open to question whether, in the absence of enteric ulcers and characteristic eruptions, it

* Being a paper read before the Indian Medical Congress and sent to the Record for publication.

is quite justifiable to call it typhoid. Again, it may mean that the germ is modified, that is, it may be a stronger or weaker germ, in which case we should expect the symptoms to be more or less pronounced, but of the same nature. It is, however, found that this cannot be the case, as true cases of typhoid fever are produced, and the germ, that is, typhoid bacillus, is obtained in India. So modified typhoid as a scientific expression must be discarded. Others name it typho-remittent fever, implying thereby that the poisons of typhoid and of malaria enter the body at one and the same time and produce their combined effects, and that according as the one poison is more active than the other in the system, the symptoms produced by that poison predominate over those produced by the less active poison. It is not quite clear which of the signs and symptoms in a case of remittent fever are to be attributed to malarial poison, and which to typhoid poison. Broadly speaking, fever symptoms may be divided into general symptoms and special symptoms. General symptoms are common to pyrexia, such as heat of the body, frequency of pulse and respiration, interference with the functions of the various organs, and disturbance of the nervous system, such as headache, pains in the body, and in severe cases acute or low delirium and typhose condition. The special symptoms are the course of the fever, temperature chart, the onset and the termination and specific lesions. Now typhoid fever will produce the same general symptoms as those of malarial fever. They are, however, more violent, because the temperature is higher and more persistent, and the poison is of a more virulent character. The special signs and symptoms are enteric ulcers, peculiar eruptions, peculiar character of stools, and a period of 21 days. There is also to be found typhoid bacillus. In malarial fever, the special characteristics are the peculiarity of the onset and the decline, the three characteristic stages, the cold, the hot and the sweating, the periodicity and the amenability to quinine, and there may be found Laveran's bodies in the system. If the term typho-remittent is to be applied to these cases of remittent fever which do not yield to quinine, the question arises, where is the combination of the symptoms? All the symptoms special to the malarial fevers, namely, the three stages, periodicity, as well as the amenability to quinine, are entirely wanting, nor do we meet with enteric ulcers or the peculiar eruptions. Even the period of 21 days, though present in some cases, is not universally found. This term is also inapt, inasmuch as it puts one on the wrong scent, and is based on unsatisfactory data. My impression is that the term at one time was applied to cases of remittent fever, in which typhose condition supervened; typho then was an abbreviation of typhose condition, and not of typhoid fever. This view that the remittent fever (excluding cases purely of an ague type) is due to the two poisons getting into and acting in the body at one and the same time is in my opinion untenable. The question then still remains unanswered, i.e., what is remittent fever? To me it appears that it is a distinct fever entirely different from malarial remittent on the one hand and the enteric on the other. It is in many cases found that the beginning of this fever dates from the inhalation of sewer gas.

In many cases, wherever it was possible, I have elicited from the patients the important information that the beginning of this fever was due to this gas. This is what the patient says: "Returned home as usual with nothing particular added in the daily routine; all of a sudden got a bad smell that made me uncomfortable; after that I felt some vague but trifling pains in the body and unaccountable depression. This state of things lasted from two to four or more days." After which the course of the fever is as follows: He begins to feel hot, without any shivering or rigor, temperature in the beginning does not go above 101° F. and continues with slight variations to rise till the fifth day, when generally it reaches its highest point which is sometimes as high as 105° F. It then continues with variations of a degree or two. At this height for about six days in some, eight in others, or fourteen or twenty-two in the rest, when it terminates by lysis. It will be seen that the full course varies from eleven days to twenty-eight days accordingly to the course it gives. We have four varieties of eleven days, fourteen days, twenty-two days and twenty-eight days. It is accompanied from the very beginning with extreme physical discomfort and prostration out of proportion to the height and duration of the fever. Sometimes there is acute delirium, followed by low muttering delirium in fatal cases. There are no eruptions and no abdominal tenderness or gurgling, stools when passed are healthy, and the face is pinched instead of having the bright circumscribed flush. There are also other symptoms of an adynamic character, such as are found in other cases of fever. This sketch will shew that, except that the temperature chart is to a certain extent similar to that of typhoid fever in some cases, though not in all, there are no symptoms which are found in the enteric, nor are there any symptoms which can be referred to a malarial origin. As I have said above, this fever is a distinct though unnamed fever, caused by some poison of microbic origin conveyed by sewer gas. It is possible that in the decomposing animal dejecta pathogenic germs of more varieties than one may be present, and that the fever we are considering may be due to the one or to the other, but it is not identical with the typhoid poison, nor has it any connection with the poison of the fever of the ague type. It may be said that this is a question more of an academic character, but even if it were so, in the interest of science, we would be perfectly justified in finding out the truth about this matter. However, it has a practical significance of a most important character. If the case should be of a malarial origin, one would be justified in pushing quinine to its fullest extent; if not, one is not justified in dosing his patient with a drug which has, in large and heroic doses, a depressant and injurious effect. If it is typhoid fever, one has to be very careful about the diet of the patient. If it is a distinct fever by itself, as I regard it, then our duty lies in striking out a new path, if possible. This question was discussed in Bombay in a series of meetings of the profession convened by the Grant College Medical Society, and has been referred to a Committee, and it is to be hoped that the investigation of the Committee will be of a decisive and practical character.

The conclusion at which I have arrived is that the cases included under the term of remittent fever cases are not

all has to one and the same cause. There are a few true resistant fever cases of the ague type, which readily yield to quinine. The bulk of these cases, however, are due to other cause of a malarial origin, which has its habitat in decomposing animal deposits, and that there are probably more than one variety of these germs which produce more than one variety of cases.

THE ADVANTAGES OF TOTAL ABSTINENCE.*

By SURGEON-MAJOR G. F. POYNTER, A.M.S.

Madras.

As educated professional men, we are required to see if there are any advantages in total abstinence either for ourselves, or for our patients; to discuss the subject in all its bearings, as far as possible with unbiassed minds and to adopt that which we honestly feel may be profitable either for ourselves or for those who desire our opinion professionally. Now I am fully aware it is not, as a rule, a very strong case that requires a negative argument for its proof, but nevertheless it is a very useful form of argument, and one that sometimes carries more weight, and is more likely to convince than a direct argument in favor of the points you wish to prove. I propose to adopt this form of argument at first and shall endeavour, as far as possible, to point out some of the disadvantages of drinking alcohol habitually before drawing attention to the advantages of total abstinence.

All the fermented liquids commonly used as beverages, contain ethylic alcohol in varying proportions, and in consequence their action on the human body varies in proportion to the ethylic alcohol, the various constituents and adulterations that these liquids contain. The chief constituent of all fermented liquids which must claim our attention is the alcohol, as it is to this substance that they owe those properties for which they are drunk.

Alcohol is the result of fermentation, which says LIEBIG, "is nothing else but the putrefaction of a substance containing no nitrogen." Ferment or yeast is a substance in a state of putrefaction, the atoms of which are in continual movement. In order to prevent this fermentation turning the liquid into vinegar, the ingenuity of man steps in, and by heat or some other method stops the process at the proper moment. The making of wine has been aptly described as a chemical process, as the albumen in the grape juice unites with the oxygen in the air, and is converted into yeast, this yeast in the vinous fermentation resolves the grape sugar into alcohol and carbonic oxide. Now let us see how this alcohol acts on the human system. If moderately diluted it is a slight irritant to the mucous membrane of the mouth, pharynx and stomach; increased in quantity, it has a reflex action on the circulation, and if largely given may cause death by bringing about a sudden rise of blood pressure, and by arresting the heart in diastole. It has also in smaller quantities, an anæsthetic effect on the nerves of the stomach, this probably accounts for the fact that it is, at times, useful in irritable conditions of that organ. Nearly the whole of the alcohol consumed is absorbed by the capillaries of the stomach and carried in the blood to the liver, where it becomes more concentrated

than when it has passed through other parts of the body. Therefore, we find that its effects are more marked on the liver than on other organs, and we get degenerative enlargement and fatty degeneration of that organ, as the result of direct interference with the liver cells and the transformation of the connective tissues, from a permeable tissue into a dense more or less impermeable tough structure, resembling parchment.

Alcohol, further, prevents the absorption of oxygen and the exhalation of carbonic dioxide from the blood. DR. PROUT states: "Alcohol in every state and in every quantity uniformly lessens in a greater or less degree the quantity of carbonic acid gas eliminated, according to the quantity and circumstances in which it is taken. When taken on an empty stomach this effect is almost instantaneous, but is probably greatest three hours after taking the alcohol. It must interfere therefore to some extent with the purification of the blood, and check all functions which require oxidation for their performance."

Alcohol at first, increases the contractions of the heart but later there is flagging and weariness due to the extra work it has to accomplish. This may be the paralyzing influence of alcohol on the vasomotor centres, the calibre of the arteries and capillaries increasing greatly a larger quantity of blood is required to fill them and the heart, consequently, has extra work to pump more blood into the enlarged channels.

On the brain and higher nerve centres the physiological action of alcohol is well known, and of great importance. These appear to be paralyzed in the inverse order of their development. The power of self-control is lost, the muscles which act almost, if not quite, automatically in the ordinary duties of every-day life become erratic and the power of co-ordination is lost. Increase the dose, and only the involuntary functions are performed, these in their turn are extinguished to be followed by profound coma and death as the result of large doses taken in quick succession. Small doses taken habitually, for years, produce anatomical changes. DR. DICKENSON pointed out that alcohol replaces more actively vital material by fat and fibrous tissue and substituting suppuration for new growth promotes caseous and earthy changes to help time in producing the effect of age. In a word it is the *genius of destruction*. DR. ALFRED CARPENTER says: "It is virulent poison, and as such should be placed in the list with arsenic, mercury and other drugs." These are strong words, but when we study the subject and see its effects on cellar-men, inn-keepers, brewers, &c., whose occupation or calling brings them constantly in contact with alcohol, e.g., although they may be strictly moderate drinkers, we realize that alcohol is indeed "the genius of destruction" to them and though it may not itself be the cause of their death, it certainly renders them more liable to contract disease, and less able to fight against it, when once prostrate, than are those who never take alcohol. The power of resistance of habitual alcohol drinkers against morbid action is lessened by the action of the alcohol on the blood and tissues of the body. This is due to the power it has of preventing the absorption of oxygen and the exhalation of carbonic oxide and, as long ago pointed out by HANDBY, SCHMIEDER and FREUZ, is the action of

* A paper read before the S. I. Branch of the British Medical Association and sent to the Record for publication.

...the system is to become a cause of disease. The action of ethyl alcohol causing a tremor of the smallest movements of the white blood corpuscles, coupled with the fact above noted, accounts for the suppurations so common amongst those addicted to the free use of alcohol, and the difficulties encountered when treating them for disease or injury. If we acknowledge that alcohol has these deleterious effects on the body in health, we have no difficulty in seeing the disadvantages and danger of taking alcohol habitually. It is an advantage to give it as a medicine occasionally, to prevent the too rapid oxidation of tissue material, but I am of opinion that it should be used much more sparingly as a medicine than it is now, even though it is not prescribed in quite the same liberal manner it once used to be.

At the Lock Hospital in London, I was informed that of a number of selected cases, treated in exactly the same way, except that half had alcohol in one of its forms while the other half had none, the latter recovered more quickly than those who had the alcohol. Its deleterious effects on rheumatism, gout, and gonorrhoea, are also well known, and yet how many, apparently forgetful of these effects, order it very freely in this class of cases. Perhaps as a luxury in health it may be used extremely moderately without causing any very apparent derangement of the tissues of the body, but nevertheless it should be used very cautiously, and certainly forbidden to those who inherit any tendency to excess. It is not a food in the true sense of the word, for a food should build up and replenish all the tissues of the body without being hurtful to any, which is not the case with alcohol. Numerous statistics and observations have proved that alcohol habitually taken is harmful in the tropics, nor is it less harmful in the cold of the Arctic regions. Experience coupled with experiments, extending over lengthened periods and carried out by able and careful observers, show that men can do more work and endure greater hardship without alcohol than they can even with the so-called moderate doses of it, which many would have us believe are absolutely necessary in every condition of life.

Another point deserving our very careful attention is the very large number of admissions into our lunatic asylums and prisons of the victims of alcohol to which a vast amount of insanity and crime is undoubtedly due and, though unable to give you accurate figures, I can affirm that it has been conclusively proved that from 2 to 3 of the lunacy of the United Kingdom is due to drinking alcohol to excess. Dr. WALMSLEY of the Darenth Asylum says that "one-fourth of all cases of insanity are due to drink." Mr. HOLMAN declared that "during the last twenty years the quantity of alcoholic beverages consumed has been doubled, and the inmates increased to such an extent that the Municipal Council has voted funds to erect as many more lunatic asylums as of containing 500 patients each." So, LOCKHART CLARKE states that during the last five years 1,300 patients had been ad-

mitted (only 1000 were admitted in the previous five years). In this number there are 1000 who are insane (4 per cent.) and 3000 who are criminals (24 per cent.). He regards crime the testimony of judges, juries, magistrates of jails, &c., is to the effect that "from 2 to 3 of the indictable offences of the United Kingdom are due to drink." In addition we have a vast amount of idiocy and feeble-mindedness amongst children clearly traceable to the intemperate habits of their parents. With reference to phthisis, M. LAMNEAU, the eminent statistician, stated that the principal causes of degeneration and destruction among the French population were tuberculosis and alcoholism. At Rouen and Havre, where the usual average consumption of alcohol is 14 litres a head, there are 402 and 303 deaths yearly from phthisis in a population of 100,000; whereas at Toulon, where the consumption is at the rate of 2 litres, the mortality from phthisis is 250.

Nor must we forget how greatly the prosperity of a nation depends upon the thrifty habits of its individuals. If there is one thing more than another that appears to scatter thrift to the winds, it is alcohol. The amount spent by moderate drinkers may be small, comparatively speaking, nevertheless that sum might be far more advantageously laid out in food or other materials which instead of doing harm to the tissues of the body would help to protect and build them up. Certainly the amount spent on alcohol by the poor, however small it may be, is undoubtedly a needless waste of money.

I am quite aware of the fact that we shall never be able to stop the sale of alcohol entirely, nor break down the prejudice in favor of moderate quantities being habitually taken, but that is no reason why we should not do all we can to stay the tide which is sweeping so many to destruction. Are we persuaded, as thoughtful men, that the disadvantages of taking alcohol habitually, are so very palpable? Then it is our privilege, nay our duty, to educate the classes and the masses as far as we can to a better and a higher standard, and when we realize what an enormous influence for good or for evil the members of our honored profession have on all with whom we come in contact, it behoves us to carefully study this important subject in order that we may be able to give a satisfactory reason for our actions, and at the same time the knowledge we may gain in the study of it, may enable us to avoid doing harm, even if we can do no good.

As there are very great disadvantages in the habitual use of alcohol, so there are very decided advantages in total abstinence. In the first place, the total abstemious avoids all the disadvantages resulting from the habitual use of alcohol. Other things being equal, he is a healthier and a richer man than the man who drinks, and is therefore less likely to end his days in the lunatic asylum or the workhouse. He is less liable to suffer from accident, less likely to give way to his passions, and he is a better law-abiding subject. The facts brought out by the returns of our Army in India as furnished to the Secretary of the Army Temperance Association by the Adjutant-General in India show that of the convicts in the Court Martial 34 were abstemious and 2,121 were phlegmatic. Taking the number of total abstemious as 20,375, and the number of

non-abstainers as 42,754; the convictions per thousand are as follows: Abstainers 4.54; non-abstainers 42.83. Thus so far as serious crime is concerned, there were during the year 1894 nearly 10 times as many convictions per mille among drinking men as among total abstainers.

3. The statistics of those summarily punished for insubordination are not so distinctly in favor of the members of the Temperance Association, though they show that the convictions among non-abstainers per thousand are almost double those among abstainers, viz., abstainers 889; non-abstainers 4,610 or 46.86 and 98.84 per thousand respectively. So much for crime. Now let us turn to the tables referring to the health of our army as influenced by total abstinence. The table has been compiled from returns furnished by the courtesy of 26 Commanding Officers of batteries of artillery and cavalry and infantry regiments for a period of six months, ending 31st March 1895, and shows that the admissions into hospital were 6.6 per cent. among abstainers and 12.0 among non-abstainers. The percentage of last year's admissions was 5.6 among abstainers and 10.0 among non-abstainers." Another point of vast importance to our army in this country and which is most materially affected by this question is that venereal diseases cause a very large number of admissions into our station hospitals. Last year there were altogether 24,184 admissions from amongst the British troops, of which 5,514 were of abstainers and 18,670 of non-abstainers, that is, the admissions amongst abstainers equalled 271.5 per thousand, whilst among non-abstainers they equalled to 375.4 per thousand. These figures leave no reasonable doubt in any mind that, so far as health in India is concerned, abstainers are much better off than non-abstainers. It is most satisfactory to note in passing that this Association is now firmly established in England, and was officially recognized by the late Secretary of State for war, through whom a grant of £500 was obtained for the one-year-old Army Temperance Association, "an unmistakable proof of the belief, at headquarters, in the value of abstinence, as conducive to the health and good conduct of British soldiers." But I am thankful to say it is not in the army only that temperance and total abstinence are advancing with rapid strides; there are a large number of medical men (more than 500,) in civil life who neither use alcohol themselves, nor prescribe it for their patients, (unless absolutely obliged to do so,) and even those, who are not total abstainers themselves, very strongly recommend total abstinence for the majority.

SIR H. THOMPSON in "Food and Feeding" writes: "I am of opinion that the habitual use of wine, beer and spirits is a physiological error, say for nineteen persons out of twenty; in other words, the great majority of the human race at any age or of either sex will enjoy better health both of body and mind, and will live longer without any alcoholic drinks than with the habitual indulgence in their use, even although such use be what is popularly understood as moderate." Dr. A. CARPENTER in the same letter to which I have previously referred writes:

"Further enquiry has satisfied me that those who wish to enjoy perfect health had better avoid the daily use of alcohol, and that there are very few forms of disease in

which its use is really beneficial. Now and then, we hear it is a powerful medicine; but its very power makes it a fearfully dangerous weapon in the hands of people generally." After such authorities my opinion I could venture to give would be out of place. Let me rather suggest that a fuller study of this subject may well repay us. Through stress of work, and when hurried, some are, at times, apt to order popular remedies, such as alcohol, more or less thoughtlessly or perhaps because they think their sanction for alcohol in some form or other is desired by the patient, and if refused will be obtained elsewhere. That alcohol is really unnecessary in a very large proportion of cases is clearly shown by the treatment of all sorts and conditions of men and women at the Temperance Hospital in London. This hospital has been in existence 21 years, during which time 10,586 in-patients have been treated, of whom 5,006 are returned as total abstainers and 5,580 as non-abstainers and unclassified. With the exception of infectious cases, all who apply for admission (provided there is room), however serious the case may be, are admitted and treated in the wards, and if infectious disease should break out in the hospital the patients are isolated and treated exactly as they would be in any other hospital. No distinction is made between abstainers and non-abstainers. During the 21 years of the hospital's existence, only 17 of the 10,586 in-patients have appeared, in the opinion of the Medical Staff, to require alcohol, and the medical officers have always had a free hand to order it if they considered it necessary. The death-rate during that time has been 6.3 per cent. During the year 1894 there were 1,044 in-patients. Of these 701 were cured, 254 relieved and 59 died, giving a mortality of 5.65 per cent.

I think it will be admitted that these are very satisfactory figures: to my mind they show very conclusively that alcohol is not required by patients in the liberal manner in which it is so often prescribed, and I am of opinion that it has often been poured down their throats quite unnecessarily, and unfortunately in very many cases it has been continued, long after it should have been discontinued, to the detriment not only of the patient's body, but also of his soul. If we realize, as all true Christians must realize that no drunkard can inherit the Kingdom of GOD, surely we must see to it that we never start any of our patients or permit them to continue, if we can possibly help it, on the downward road which leads to the drunkard's grave; rather by our example, by our words of counsel, let us stand shoulder to shoulder with the clergy and fight against this evil. What is more we must not stop at moral persuasion only, there are many cases where moral persuasion is useless, they need compulsion. I look forward to the day when not only a local veto bill will be made law, and the sale of alcoholic liquors very much restricted, but I also look forward most eagerly to the day when the habitual drunkard will be confined, and prevented from being a curse to himself and his family, and a nuisance to his neighbors. We must look to prevention, coupled with high moral training if we would rid our land of the curse of alcohol.

PERFORATION IN ENTERIC FEVER: ITS SURGICAL TREATMENT.*

By FREDERICK HOLME WIGGIN, M.D.

Visiting Surgeon New York City Hospital (B. I.) etc.,
* New York.

Typhoid is no complication of enteric fever more dreaded by the physician than perforation which occurs in about two per cent. of all cases. Its most frequent causes are improper diet, distension of the bowel from any cause, or too early and sudden movements of the patient. It is present as often in mild cases as in those which are severe, and is most frequently met with in young adult males. As is well known, its recognition is not difficult. Its occurrence is announced by the advent in the course of the fever of sudden severe pain in the right iliac region, accompanied by symptoms of collapse, this being soon followed by the symptoms of peritonitis, and almost invariably on the second or third day the case terminates fatally. The site of the perforation is generally found to be in the last twelve inches of the ileum.

The late Prof. Loomis, in the course of the discussion on Dr. REEVE's paper on typhoid fever, said: "I do not remember to have seen a single recovery after there were unmistakable evidences of intestinal perforation. Recovery from a localized peritonitis, complicating typhoid fever, is not uncommon, but when characteristic symptoms of intestinal perforation are present, in my experience a fatal issue soon follows." With such evidence and our own individual experience of the hopelessness of the patient's condition when reliance is placed on Nature's efforts at repair, (spontaneous recovery resulting less frequently in this than in other forms of perforation, on account of the central location of the injury), it is not to be wondered at that with the constant reports of successful operations for the relief of perforation from other causes and in other locations, the physician should turn toward the surgeon, asking if, among the good tidings modern surgery is proclaiming to many sufferers, there is not some message of hope for the unfortunates whose condition we are considering, who seem at present to be condemned to an untimely death, and by whose bedside he has so often stood with folded hands, helpless to aid them. Said Dr. BONTECOUR, of Troy, New York, the first in this country to operate for this form of perforation, in the course of the discussion on Dr. J. EWING MEARS' paper, "I claim that when this mortal accident occurs, laparotomy cannot impair, but may improve the patient's chance of recovery." Said Dr. VAN HOOK, in his admirable paper reporting the first successful case of operation for perforation occurring in the course of a closely diagnosed case of enteric fever: "It is strange, nevertheless, that a question involving the only promise of help for five and seven-tenths per cent. of all those dying of typhoid fever should not have excited even mere interest and discussion." Dr. ROBERT ABBE, in a recent report of a case, also successfully operated upon (*Medical Record*, January 5th, 1895), said: "Why one class of cases should be left to die, while we operate on all appendicitis cases, when perforation can be recognized, does not appear."

Again, said Prof. KUSMAUL, of Strasburg, some time since: "Granted that the chance of a successful issue is heavily against you, that the patient is in the midst or at the end of a long sickness, that his tissues are in the worst state to stand the injuries of the surgeon's knife, that the lesions of the gut may be extensive, that the vital forces are at the lowest ebb, no one yet has hesitated to perform tracheotomy in the laryngeal complications of enteric fever which require it to save life, for those reasons."

With this testimony and much more that could be offered in favour of operation, one cannot help being surprised in looking over the literature of this subject, to find on record only twenty-four cases, of which six recovered. If those cases are rejected in which there is doubt of the diagnosis, we find only seventeen cases where an attempt has been made to relieve the patient's desperate strait by surgical means. Of these three recovered. Allusion has already been made to the first and third, and the second recovery belongs to Dr. NETSCHAJAN, of St. Petersburg, (*Medical News*, Dec. 1st, 1894). The writer's opinion, formed after a careful study of the subject and from a considerable experience in abdominal operations when the patients were septic and consequently in bad condition, is that the physician on taking charge of a case of enteric fever should prepare himself to act with promptness on the occurrence of perforation. It is well to remember that while there should be the least delay possible, these patients rarely die in the first state of collapse, and that this condition is not one favorable for operation. The patient, as soon as the diagnosis is made, should be stimulated by means of strychnia and morphia. If the patient rallies then the operation should be performed without loss of time and under favorable conditions there is a fair chance of success, especially in those cases in which the course of the fever has been mild or where the perforation has occurred during convalescence. Of course, if the patient refused to respond to the stimulation, the operation would be useless. Dr. ABBE, in the paper previously alluded to, said: "Very essential do I consider it that the surgeon should never be so hasty in getting at his work that he enters upon it handicapped by poor assistance, poor light or poor arrangements for irrigation." While the patient is being stimulated, the necessary arrangements for the operation can be made. The writer's experience has shewn him that a laparotomy, although the personal care and trouble is greater, can be even more safely performed in a farm-house with good surroundings than in a city hospital. All that is requisite is a clean light room, without carpet or furniture, except two or three wooden tables, an abundant supply of hot and cold soft spring water which has been sterilized by boiling, and a dozen towels.

Patients of this class do not bear anaesthesia well, and in fact the great danger comes from this source. With a closed inhaler of the Clover type, or Dawbarn's modification, which the writer has used with satisfaction for some years, patients can be readily anaesthetized and kept unconscious for an hour with four ounces of ether. The incision should usually be in the median line between the umbilicus and the pubes, rather than over the site of the pain, true as this guide generally is to the point of

* Read at the 103rd annual meeting of the Connecticut Medical Society and before the *Record* for publication.

operation, for some days after the abdominal wall is closed, the patient should be kept in the prone position. Search should first be made in the folds, because of the small gut and extravasated material in the folds of the cavity, as has been pointed out by Sauerbrey. If the intestine and perforated intestine is not found here, the omentum should be sought, and the last part of Sauer is then easily located and looked over. When the injured point is found, the perforation should be closed, if possible, by Lambert's or Heister's mattress sutures and should then be covered by an omentum graft. The sutures for closing the abdominal wound should now be placed, all the layers of this wall being included. These sutures should be of silk worm gut. When this has been accomplished, the abdominal cavity should be freely irrigated with a hot saline solution, (half a dram to the pint,) about two gallons being used, the temperature of the water being from 110 to 115°F. according to the degree of shock the patient is suffering from, and in most cases the abdominal cavity should be left filled with the irrigating fluid, and the sutures already passed should be drawn and tied. If effort has been made by nature to shut off the perforated point by adhesions, before they are disturbed the general cavity should be shut off by sponges or gauze. In some cases all that would be advisable to do would be to draw the perforated intestine into the wound and after free irrigation of the abdominal cavity it should be stitched to the wound or surrounded by gauze, further procedure being delayed till a future occasion. In a still more desperate case, one occurring earlier, when the fever was at its height, or in which the fever had run a severer course, one might with the aid of cocaine anesthesia rapidly open the abdominal cavity over the site of greatest pain, and after irrigating, surround the perforated intestine by gauze, thus shutting off the general cavity, favoring the formation of adhesions, and securing drainage, as has been suggested by my friend, Dr. E. D. FERGUSON, of Troy, N. Y. In one of the successful cases previously alluded to, NITCHAJAN'S, a portion of the perforated intestine was excised, and now that an anastomosis by means of the Murphy button can be easily effected in five minutes, it may in favorable cases, especially in those in which a number of ulcers are near together and in a dangerous condition, be quicker and wiser to excise the diseased intestine. The decision as to the best procedure must be determined by the circumstances of each case and by each operator for himself. It is here that skill and experience count for the most. Personally, I favor closing the abdominal wound after free irrigation, leaving the abdominal cavity full of the hot fluid, as I know from many past experiences how much this procedure does to lessen shock and to prevent the danger of septic infection of the peritoneum. If at this time shock were still great, it would be wise to follow Dr. ASKE'S advice to administer an enema of black coffee and whiskey on the operating table.

of the patient, as well as the patient's wishes and desires. The surgeon's primary concern is to save the life, and the surgical procedure should be the one which offers the best hope of recovery to the patient. The surgeon must be sure that the chance of a successful outcome of our work increases with every minute of delay and every minute saved. Finally, the physician must realize fully that the surgeon is his assistant and not his rival, and must give him as well as the patient a fighting chance. By calling him early and not after several days of treatment, which has too often been the case in this and other forms of intra-abdominal disease.

INFANTILE SCURVY IN CALCUTTA.

It is generally believed that scurvy is a disease peculiar to adult life, and that children, especially of the well-to-do classes, enjoy an immunity from it. I share in this belief, till four years ago, when a case came under my observation, which, for the first time, excited the suspicion that it might exist amongst Bengalee children, though the symptoms may not, at first sight, lead us to a clear perception of its identity. Since then I have been able to gather facts which leave no doubt in my mind that the disease is more common amongst Bengalee children in Calcutta than we are aware of. I will read notes of three cases which I consider best calculated to establish my position. The treatment adopted, having been essentially the same in all the three cases, will be mentioned briefly at the end.

*Using a report sent before the House Military Committee and sent to the House for publication.

continued, and the child continued to be fed on barley gruel, in spite of our remonstrances against it. He resisted this injudicious dietary for some time more, at the end of which the true nature of the disease revealed itself in extensive ulceration of the gums and the appearance of hæmorrhagic spots on both legs. Blood was also observed in the evacuations. Rapid emaciation followed, and symptoms of rickets manifested themselves. The lower ends of both tibiae became swollen, and the epiphyses separated from the shaft after some time. From this period till the age of nearly two years, the child's life was one of alternate deterioration and improvement, and it was only by the adoption of a most careful dietary that all traces of scurvy were finally removed from his system.

My second case was that of a male child, aged about eighteen months, who had out nearly all his temporary teeth, and had learned to walk. His father, a medical man, being absent on duty, and his mother being in confinement, he was left entirely in the hands of a nurse—an unscrupulous woman who was utterly unfit for the charge. It was afterwards found that she was in the habit of drinking most of the child's milk and of adding water to it to escape detection. When first called to see the child, I was told that he was suffering from infantile paralysis, and was being treated for it. On examination, I found the child able to stand, but the effort was evidently painful, the muscles (especially of the lower extremities) were flabby, and the skin had a rough, oldish appearance. On close examination purpuric spots were found on different parts of the body. The temperature was 100°F., and the child cried whenever an attempt was made to lift him from his bed. His breath was very foul, and there was extensive ulceration of the gums, which were hanging loosely in several places. I at once transferred the child to the care of a kind-hearted and intelligent lady of the family, under whose supervision, and with the aid of a generous diet, the child was restored to its usual health in less than two months.

My third case is still under my treatment. It is that of a female child, aged thirteen months, who has been deprived of her natural food, owing to the mother being the subject of pernicious anæmia since she was brought to bed. As in the preceding case, the child was left to the tender mercies of an ignorant nurse till the age of ten months, when she had an attack of strong fever with bronchitis. In the course of a week she was found to lie all day in bed, with hardly any power to move her limbs. It was at this stage that I first saw her suffering from most of the symptoms detailed above. The lower limbs were flaccid and painful to the touch; the shaft of the right femur and the lower ends of the tibiae and radii were swollen. The temperature varied between 102° and 100°; petechiæ were found in several parts of the body, and the characteristic ulceration of the gums was largely present. An alteration was at once ordered in the diet of the child, and she is now in a fair way to recovery under the immediate supervision of her mother.

The treatment in each of these cases was essentially the same. The child was fed only on fresh cow's milk, peptonising it whenever digestion was found to be deficient. The juice of fresh fruit, especially orange and pine-apple, was given three to four times a day.

Later on Scott's emulsion of cod liver oil with Parfitt's chemical food were given with great advantage. The condition of the gums was rectified by close attention to cleanliness and by the application of boroglyceride with glycerine. I ought to mention that the ulceration, as also the petechiæ, disappeared in each case after the child had taken orange and pine-apple juice for only a fortnight. Due attention was paid to the child's clothing, and it was daily taken into the fresh air as soon as it was found strong enough for it.

That the disease in each of these cases was scurvy a few words will suffice to prove. The ulcerated condition of the gums and the presence of hæmorrhagic spots in different parts of the body, distinctly point to changes in the blood, which can be induced by no other pathological condition known to us. The swellings of the long bones may indeed, raise in our minds a suspicion of rickets, but these appeared long after the other two characteristic symptoms had manifested themselves, and might, therefore, be dismissed as secondary results. Rickets, as we all know, is a disease usually associated with poverty and hereditary syphilis, but in none of my cases was either of these causes at work. Nor has it ever devolved with such rapidity as in the instances I have quoted. But what I believe to be the surest proof of all was the rapidity with which the scorbutic symptoms disappeared after the administration of the juice of oranges and other fresh fruits.

PATHOLOGICAL, ETIOLOGICAL, CLINICAL AND THERAPEUTICAL REMARKS ON THE PYREXIAL STATE.

BY SURGEON-CAPIAIN PATRICK HEHIR, M.D., F.R.C.S.E.,
F.R.C.S.E., D.P.H. Cantab.

*Lecturer on Medicine and Pathology, Hyderabad
Medical School.*

(Continued from page 310 of Vol. IX.)

WE pass on to speak of another highly interesting form of pyrexia which, for want of a better name, or clearer knowledge, we call *urethral fever*. In some persons the passage of a catheter causes an immediate rise of temperature, sometimes accompanied by a rigor which cannot be due to inflammation. In both the last mentioned cases it seems clear that the effect is too rapid to be due to the absorption of any pyrogenic substance from the wound or urethral surface, and that there must be some stimulus transmitted through the nerves, which probably exerts a reflex action on the central nervous system. In tetanus high and sometimes excessive temperatures have been observed. WUNDERLICH records a case where the temperature was 112.5° at the time of death. Now although tetanus must be regarded as a specific infectious disease, and therefore the rise of temperature may be partly due to the morbid poison, still the affection of the spinal cord and the excessive muscular contractions must be credited with part, at least, of the resulting pyrexia.

In all the above lesions and pathological states, therefore, we have evidence of the production of pyrexia from some injury to nervous system, central or peripheral.

It should be remembered that "shock" is often an important element in these cases, as the injury producing

we can see that the pathologic condition is a physiological experiment, but especially factors are at work—out, chiefly to the temperature mechanism, causing loss of heat from the surface, and another which may be referred to the calorific centre, causing increased production of heat. Sometimes one of these factors has the predominance, sometimes the other.

Shock is meant a condition of which the most characteristic feature is a loss of tone through the whole arterial system; that is precisely the condition which, as we have seen, physiology teaches to be the cause of excessive dissipation of heat, or rapid cooling. In the cases referred to, we must therefore suppose that the loss of heat due to shock more than counterbalances any gain of heat due to injury of the heat-centre or its efferent fibres. Ill-defined degenerative changes in the brain are also sometimes accompanied by a fall of temperature, of which the explanation may be the same. But even these facts are evidence, in any case, of the calorific mechanism being interfered with by injuries to the brain, though in a converse sense to those formerly spoken of. It should be stated that after the fall of temperature caused by shock, however produced, there is very generally a reaction causing a rise, and this rise may possibly be independent of any other lesion of the nervous system.

In another series of cases, similar injuries have produced a fall of temperature. Mr. HUTCHINSON has recorded a case of fracture of the fifth cervical vertebra, where in the rectal temperature a fall to 95.8° was noted. Injuries below the first dorsal vertebra appear never to have been observed to be followed by excessive lowering of temperature. But no general law has been traced, which determines why there is sometimes a rise and sometimes a fall.

Injuries to the cord, commonly from fracture of vertebrae, produce sometimes a rise, sometimes a fall, of temperature.

Many cases of remarkable rise of temperature have been recorded since Sir B. BRODIE's famous case of injury to the cervical portion of the cord observed in 1837, when the temperature was 111°. After fracture of the cervical or sometimes of the dorsal vertebrae temperatures ranging up to 110° or more have been observed.

Another product of our defective acquaintance with the intrinsic pathology of pyrexia is the term *traumatic fever*.—It has often been observed that high fever results from wounds, apparently without inflammation, or at all events out of all proportion to the amount of inflammation. Numerous cases are recorded in surgical works, and only one typical instance need here be quoted. In a case of amputation of both legs for crushed feet recorded by Mr. LE GROS CLARK, the temperature rose from 105° seven hours before death, to 110° a quarter of an hour before death, and was 110.8° a quarter of an hour after death. These cases, then, are different from the traumatic pyrexia caused by absorption of pyrogenic substances from unsanitary wounds.

Mr. HORSLEY has suggested that the term *traumatic fever* should be restricted to the pyrexia ensuing upon a simple injury uncomplicated by septic infection. Such a simple injury would predicate a break in the chain, but the absence of exposure to pyrexia-producing conditions. He suggested that the fever of traumatic origin might be placed in fever categories, (a) simple-traumatic

fever, and (b) septic fever. Amongst cases covered under pyrexia conditions which may be said to be wounds treated upon antiseptic principles, in connection, the lecturer quoted Volkmann's view, that a fever-producing substance is developed at the seat of injury and then absorbed into the circulation. Mr. HORSLEY would separate cases of simple fractures from amputations, since in the latter there are chemical substances in immediate contact with a large absorbing area. Mr. HORSLEY suggested that the cases should be divided into two classes, viz: (1) those in which a rapid rise of temperature occurred with but little swelling, and (2) those in which much swelling was present with only a slow rise of temperature. Studying charts constructed from the first class of cases, he found that a sudden pyrexia occurred in the first hour, followed by a more gradual rise for twenty hours; then lysis supervened, which was complete in about a week. In some cases, the initial rapid rise extended over several hours, and de-cleason was quite complete in 48 hours. The first group occurred at an earlier age, in fact, where tissue metabolism was more active. In the second class a rapid initial rise to 100° was followed by a steady rise to 101°. On the third day, remissions being present. A fall to 99° then occurred, and this was almost invariably succeeded at the 112th hour by a second rise to 100°, when a steady fall brought the temperature to normal, in from two to three days. In duration these cases varied from 7.5 to 12 days. These cases occurred among the young and old, whose tissues, it would appear, were more obnoxious to injury. To this conclusion the presence of marked swelling would also point. Study of these cases led Mr. HORSLEY to suggest the following possible sources of fever. A stimulation of afferent nerves as by rubbing of fractured bone ends; absorption of extravasated blood; the existence of fat-embolism. Experiment shewed that while severe stimulation of afferent nerves causes depression, slight stimulation occasions elevation of temperature possibly by the agency of heat centres in the cord. Again, ANGERER produced artificial hematomata, and found pyrexia rapidly following. To explain the second class of cases, Mr. VICTOR HORSLEY cited experiments which, he contended, went far to prove that the development and absorption of the swelling were factors in establishing the slow rise of temperature which occurred in them.

The subject of *urethral fever* formed the fourth of the BROWN lectures of the Royal College of Surgeons, which lectures were given recently by Mr. HORSLEY. He thought it impossible that this fever could be of other than of septic origin; its rapid appearance, usually in four hours, and its supervention upon simple catheterisation without abrasion, rendered untenable the theory of a septic pathogenesis. Urethral fever he divided into two varieties, an acute, fulminating, occurring usually from catheterisation, and (2) a sub-acute fever occasioned by internal urethrotomy. The fulminating variety occurred mostly in patients who were under treatment for the first time, and whose stricture was of recent formation. The rise of temperature in the acute form was much slower, being preceded by a sub-acute drop of 1°, due probably to shock. The maximum temperature

...the first of cases occurred... the subject of stricture for... and... had treatment... which was the immediate antecedent of the fever. In cases in which no pyrexia supervened upon treatment, Mr. HENLEY found that the stricture had always been of very long standing, with a history of previous extensive treatment. To explain the pathogenesis of urethral fever, he introduced the hypothetical heat-centres in the spinal cord. The researches of QUINCK, NANNY, WOOD, HEIDENHAIN and others, rendered it probable that such centres do exist, and are in all likelihood thermo-inhibitory in nature. In a urethra crippled by a recently formed stricture, the nerves would be highly sensitive, and would readily respond to stimulation, and hence reflex heat changes would in such cases naturally be initiated, while in long-standing stricture, the sensitive character of the urethra would be considerably impaired,—a result also largely brought about by previous manipulation. The evidence was, in Mr. HENLEY'S opinion, altogether opposed to SEDILLON'S septic theory, and lent itself readily to one which appealed to a neurotic origin. Thus chloroform, ether, morphia, quinine, which could not exert any influence upon septic absorption, controlled alike the rigors and the pyrexia which, without their employment, ensued in surgical manipulation of the urethra. Drawing practical conclusions, gradual dilatation with internal urethrotomy appears to be the procedure most free from the risk of pyrexia. He advised that chloroform should be administered, the urethra dilated to No. 4 E., and internal urethrotomy then performed. No instrument should be left in the urethra; nor should one be passed for 96 hours after the operation, and recourse should be had to quinine for the after-treatment. The urine in these cases was somewhat lessened, but rapidly returned to its normal standard.

A MIRROR OF PRACTICE.

THYROID EXTRACT IN PSORIASIS PALMARIS.

By CHARLES FORBES, M.D.

Late Surgeon, N. G. M., West Africa.

August 30th, 1894.—C. A., a strong healthy, looking lady, *æt.* 36; about 5 feet 3 inches in height, weight 15 st. 6 lbs. consulted me regarding an eruption in the palm of her left hand which, she said, had existed for about 14 days; she complained of constipation; the cutaneous eruption was dry, harsh, and scaly (strongly typical of psoriasis); she also remarked that she had never had any other form of skin disease.

Previous History.—During childhood had been attacked with acute rheumatism, and her early life had been sickly but on growing up appeared to be quite healthy, had worked hard, etc. Had first noticed a hard dry scaly appearance in left palm in November 1893, but it had died away shortly afterwards on applying various ointments. She also noticed since November in that year her hair had been falling out. She had also on thyroid extract *gr.* three twice a day; but she complained of nausea and slight indigestion, eruptions more marked, and declared the

kind medicine was most disagreeable. I put her on thyroid gland powder (equal to 1/4 of a fresh gland three times a day).

September 7th.—I found her much better (she had taken 9 doses), slight thyroiditis had set in. Temperature was 100°F. and Pulse 92, more lively and active in her movements, no change in eruption except that it seemed redder; thirst; amount of urine passed during the day increased.

September 10th.—P. 84, T. 99°F., still very thirsty, perspiring freely, bowels opened every day since the 7th, says she is passing about twice as much urine as usual, feels very bright and well. Scales in left palm beginning to desquamate. Hair does not come out so freely as before, and her face looks slightly thinner; weight 15 stone 5 lbs.

September 17th.—P. 80, T. 98. Has not complained of nausea; tongue not coated; no headache; still bright and active; bowels regular every day; appetite good; face thinner; urine still abnormal in daily quantity; hair does not come out at all; still perspiring freely; weight 15 stone 3 lbs. 6 ozs.

September 24th.—P. 76; T. 98.6°F., not perspiring as freely; bowels regular; tongue clean; general health good; eats well; sleeps well; face markedly thin; panniculus adiposus diminished; downy hair growing on both forearms which had been previously quite devoid of hair; weight 15 stone 11 lb.; no sign or trace of eruption in left palm; skin normal. Thyroid treatment was now abandoned.

February 3rd 1895.—Again saw this patient; face a little fuller; feels quite well and speaks highly of the medicine. Weight 15 stone 2 lbs. No recurrence of psoriasis eruption.

Remarks.—I was led to adopt the thyroid treatment in this instance by the success attained with this drug by Dr. B. CRANWELL in a case published in the *British Medical Journal* of 29th March 1894.

Psoriasis of the palm in one hand only is known to be a most obstinate and intractable form of this disease which is, as a rule, but little affected by local or general treatment (unless specific) which, I am of opinion, should be excluded in the present case. It might, I think, be rightly ascribed to excess of uric acid in the blood as this patient's history denotes; for she was often subject to slight urticaria, probably toxicemic in origin.

—:—

A SUCCESSFUL OPERATION FOR IMPERFORATE ANUS.

By F. THUMBOSWAMY PILLAI, C.M.S.

Deolgaon, Raja, Berar.

On the 24th May 1895, at 8 p.m., I was called upon to see a new-born male child who had not defecated for about 12 hours since birth. The child was lying semi-conscious and frequently vomiting a watery fluid, and occasionally crying for a few seconds. The abdomen was tympanitic and urine was passed during the efforts at vomiting.

On looking for an anus, I observed a dark circular and wrinkled spot situated in the place for the anal orifice but having no communication with the bowel. The oval surface was flat, not bulging at all, even when the child attempted to vomit or cry.

A longitudinal incision, about half an inch long, over the dark circular wrinkled spot, was carried high up to about 2 inches, obliquely upwards and backwards using the left little finger as a guide to avoid injuring the large blood vessels in this region. Then a search was made with the finger for the lower end of the rectum, which was felt like the movement of a round worm, i.e., moving free. This was seized with a pair of dressing forceps, brought down as far as the external opening of the wound, by means of gentle traction upon the bowel and its edge being first stitched to the margin of the wound with four silk sutures a free opening was then made into it, with the point of the scalpel, sufficiently large to readily allow a free discharge of its contents. About 2 ounces of meconium were passed and the little patient was at once relieved from the urgent symptoms of vomiting and tympanitis.

The subsequent progress of the case was very satisfactory. On the third day after operation the sutures were removed as the union was perfect, and the rectum, as well, showed no tendency to be drawn up. Bowels were kept open and regular by occasional doses of castor oil. Carbolic oil (1 in 20) was frequently painted over the external wounds for a fortnight; at the end of which period the wound healed up, leaving a permanent passage with no tendency for the opening into the rectum to close up again.

—————:O:—————

THREE CASES OF STRAMONIUM POISONING RECOVERY.

By MOHAMMUD KABIRUL HASUN, C.M.S.,
Pisangan Dispensary, Rajputana.

On the 19th May 1895, at 1 P.M., three patients from one family were brought to my hospital by the police who stated that at 11 A.M. they had eaten bread of jand herb and of baigun and laid down to sleep for a short while, and when they got up their heads swung and their ideas were confused. On examination, I found them suffering from various degrees of stramonium poisoning:—

(1). RAM NATH *at* 30, a previously healthy and laborious man. His ideas were confused or mixed, conjunctive blood-shot, pupils dilated, face red, power of speech lost, pulse feeble, involuntary motion of the body, cannot walk properly, and all the other symptoms of *dhatura* poisoning, but not very severe.

(2). MATI, *at* 27, the wife of RAM NATH, was a weak woman whose condition and symptoms were the same as of the above patient but very severe, and she kept on picking at imaginary straws from the ground.

(3). RAM PERHAD, *at* 3, son of RAM NATH was a strong healthy child, exhibiting conditions and symptoms similar to those of his father but less severe.

Treatment; I gave an emetic of zinc sulphate, and after a few minutes had cold water continually dashed on their heads and faces, in open air, till 3 P.M., when RAM NATH and his son were quite well, their pupils normal, speech clear, pulse regular, no involuntary motion in body and all the bad symptoms had disappeared; but as MATI was not quite well, the same treatment was continued till 4 P.M., when she recovered consciousness and as there were no further symptoms of poison I let them go home, at 5 P.M. and advised them to use thapsus (i.e., saunf, kandi, rose &c.)

COMPLETE CONGENITAL OBSTRUCTION OF ANUS. OPERATION: RECOVERY.

By AMT. SUDEN. KHALIFA RASHID-UD-DIN, M.B.,
Civil Medical Officer, Chitrawa, N. W. P.

A FEMALE infant, a day old, was brought to me, in the Sandila District, Hardoi, Oudh, in September 1893, with the complaint that since her birth she had not passed anything by the bowel.

On examination the site of the anus was found completely closed by a thick membranous septum. There was a faint mark of the raphe along the central line, and a slight depression through which, after a little difficulty, the dark meconium could be seen, and on which an impulse could be felt.

Operation.—One incision was carried through the septum along the middle line, and two across on either side; after which the meconium escaped freely. The four angular flaps were then removed, and complete recovery obtained by the use of oiled plugs. There was no other malformation.

Remarks.—This form of malformation, although not very rare, is interesting, on account of its non-accompaniment, in this case, with any malformation of the external genitals or other organs.

—————:O:—————

POISONOUS SYMPTOMS FOLLOWING WASP- STING: RECOVERY.

By JOSEPH BENJAMIN, C.M.S.,
Medical Practitioner, Ahmedabad.

On the 16th March 1895, a few Parsi families went to see the Clock Tower at this place and were swarmed upon by large numbers of wasps that stung them on the head, face, ears, neck and hands. One of the ladies, two gentlemen and a boy were severely wounded, while all of them were in intense agony and restless. The lady was unable to speak for some time, and one of the gentlemen kept tossing his head about wildly. The heads, hands and faces of all these patients were greatly swollen. Shortly afterwards all of them were seized with vomiting and diarrhoea which ceased the next day. They were treated with laudanum and salvolatile internally and lead lotion externally.

Remarks.—These cases are reported because in all the patients vomiting and diarrhoea supervened after the sting a phenomenon not generally accompanying wasp-sting.

TREATMENT OF DIPHTHERIA.

ABUNDANCE of sunshine, the greatest of all purifying agents and germicides, good hygienic surroundings—absolute cleanliness indoors and out, internal and external—are axioms, so to speak, which should form the basis of treatment in all cases. When the disease has appeared in any locality the whole population should be informed at the earliest possible moment, so that suitable precautionary steps may be taken to suppress the outbreak. The mouths and throats of all children under fifteen years of age in the infected district should be carefully examined from day to day. DOCTOR DU CROUX, in *Journal of Medicine*.

THE Indian Medical Record.

16th November, 1895.

THE MEDICAL PRACTICE QUESTION IN INDIA. SOME FACTS ABOUT OFFICIALS AND PRIVATE PRACTICE.

THE *Indian Medical Gazette* ventures in a very feeble and impotent manner, to pose as the apologist and advocate of medical officialism in India. It has proved itself utterly incompetent for so grave a cause, which certainly needs both an apologist and an advocate. Whatever our contemporary may have to say upon sanitation we are prepared to receive as coming from an organ thoroughly conversant with its text, but its utterances on the "Medical Practice Question in India" display the most lamentable ignorance of the subject. This want of knowledge is but natural, for one must be in the actual every-day practice of his profession to know anything of the details that concern the matter of income from such a source.

The *Indian Medical Gazette* writes as follows:—"With reference to the attention that is being drawn in the Press to the large amount of private practice obtained by officers of the Indian Medical Service in Lower Bengal, we think it will be useful to throw a little light on the actual position of affairs, wherein it will be seen that the prospects instead of being so brilliant and prosperous as described, are very poor indeed. Some years ago, the chief inducement for officers of the Indian Medical Service to enter the Civil Service of the Government of Lower Bengal, was the hope of securing, after some time, an appointment in Calcutta. With the exception of Dacca, Bankipur and Darjeeling, there was nothing else to look forward to, and officers made up their minds with this object in view, to pass a lonely life for years in an isolated and small unhealthy and malarious station, surrounded by paddy-fields, with little or no European society. Private practice did at one time perhaps help to compensate in some degree for this isolation, but whatever may have been the case in former times, we are in a position to state as a fact, that today the so-called private practice in the majority of cases is practically nil. o o o

With loss of private practice, the fall in the value of the rupee and increased cost of living, the civil branch of the Indian Medical Service is far from being the highly favored service it is represented to be, while the block in promotion to the administrative ranks, which it is at present suffering from, if it continues, will likely, when it becomes known, render the service still less attractive. Instead of it being the rule, as was the case some 20 or 30 years ago, that promotion to the administrative ranks took place either before or at about the 25th year of service, the average period is now from 30 years or more. True, a few men have attained administrative ranks recently at an earlier period, simply from the fact that there was a period of five years between 1860 and 1865 during which no officer entered the service, but we are now referring to the general rule."

Now with regard to this somewhat lengthy quotation from the *Gazette*, we would remark as follows:—

It is full of misrepresentations, inasmuch as in the first place, the question of private practice, concerning which there has recently been so much agitation in the medical and lay press, refers to large cities in India, and not to small stations in Lower Bengal, so that the dismal picture or simile, drawn by our "knowing" contemporary, in which it likens the lonely official to the "solitary bogie in the paddy fields" is too far-fetched to inspire sympathy. Everyone knows the delightful social life of mofussil stations, and how really enjoyable is the early portion of the junior civil surgeon's sojourn among these delightful experiences. Time would wear very heavily on his hands were it not for the tennis parties, shooting excursions and other jollifications that form the sum total of civil official life in almost every mofussil station throughout India. Every civil surgeon will allow, that to describe his daily life as a monotonous, routine of hard, dry-as-dust medico-legal experiences, mixed up with toil and labor, causing his life to be a burden, is simply nonsense.

Of course he signs a lot of papers and forms, inspects a jail, spends an hour at the miniature hospital or dispensary; once in a year or two he rides through his district, —a pleasant and necessary plunge for his liver—but who among our Civil Surgeons will fail to admit, that the bulk of the work done in his district for which he magnanimously accepts all the credit, is really done by the Assistant Surgeons and Hospital Assistants under his orders. These are facts and are very different from the picture of the lonely, disconsolate, malaria-threatened Indian Medical Service Officer "in the paddy fields."

The *Gazette* says:—"Private practice did perhaps at one time compensate in some degree for this isolation (in the paddy-fields of course) but whatever may have been the case in former times, we are in a position to state as a fact, that to-day the so-called private practice in the majority of cases is practically nil." We have italicised what we feel as a fact to be anything but a fact—in fact this so-called fact is a hideous deviation from the truth. We would challenge the *Gazette* to prove its so-called "fact." There is not a single official practising in Calcutta who makes a farthing less than two thousand rupees in addition to his monthly pay, while there are three or four among them, whose income from private practice equals the monthly salary of the Lieutenant-Governor of Bengal! If in the estimation of the *Gazette* a monthly income of from two to six thousand rupees, is a practical "zero" or "nil," then of course mathematical calculations have lost all their logical significance. We know as a "fact" that one of our junior official practitioners has no less than seventy-two families on his regular list of family-patients, that some of these families are accepted on annual fees of Rs. 150 and Rs. 200, and that one or two of our worthy official practitioners have openly made it their boast that their monthly income from private practice varies from four to six thousand rupees! Had our contemporary read in the lay press the jubilant and beautiful description concerning official practitioners and their "primes" emanating from the pen of an official, it would have greatly modified its dogmatic assertion, namely:—"We are in a position to state as a fact." The fact

and the higher posts, which are the right of Government officers, to be given to the able and other persons. It gives a diametrically opposite conclusion to the result. Our contemporary grows impatient with the Government to make administrative appointments and to make the efforts that make the ascent to a higher sphere from a "professor" and official (private) practitioners to Inspector-General or P. M. O., a slow and lengthy one. This, too, is a pitifully impotent plan, for as a matter of fact, when promotion comes and is offered to these "professor" practitioners, they as a rule either allow promotion to slide, or they shirk its responsibilities by retiring from the service.

But having regard to our contemporary's assertion that private practice for officials in Calcutta is to-day "practically nil," we would beg to suggest that in view of its own declared policy, the Government shall not permit its servants to engage in private enterprise and thus to vitiate their own legitimate duties and at the same time handicap the aspirations of private individuals whom the Government is bound to protect. We say that in view of this declared policy, the Government has a perfect right to call upon its medical servants who are engaged in private practice in the metropolitan cities of India, to send in a true and complete statement of their monthly income from private practice and the nature and sources from which this income is derived, namely:—families, schools, trading houses, insurance offices and such like. We feel sure that such a demonstration of the real facts of the case would instantly compel the Government in simple honesty to the public interests, to prohibit medical officials from engaging in private practice, for then it would be revealed that official duties for which large salaries are paid from the public exchequer, were being sacrificed wholesale in the greed for making money.

If what the *Gazette* affirms turned out to be true, the scandal, small as it might then be proved to be, could be swept away without the faintest ground for complaint that to deprive professor-practitioners of what was or is "practically nil" is no hardship at all.

—10—

THE MADRAS PROTEST AGAINST DR. HART'S CRITICISMS OF THE I. M. S.

SINCE penning our article on the agitation that has been proceeding among the members of the Indian Medical Service as a result of Dr. ERNEST HART's address before the Public Health Section of the British Medical Association at its annual meeting for 1895, we have had the pleasure, or rather we should say the satisfaction, of perusing the proceedings of the special meeting of the South Indian Branch of the British Medical Association—a meeting at which a strongly worded protest was adopted with acclamation, to be forwarded to the representative of the branch in England, in order that steps may be taken to prevent the Editor of the *British Medical Journal* from defaming the Indian Medical Service, many members of which are also members of the British Medical Association.

There is a feeling that Dr. HART has painted matters very much blacker than they are, and in so doing has placed the Indian Medical Service in a very un-

favorable position before the public. It is true that, as our previous article has shown, we are very far from Dr. HART's intention to disparage the members of the Indian Medical Service; but that it is his earnest desire to alter, if possible, the system of medical and sanitary organization obtaining in India. That the alteration is a pressing necessity is our positive conviction, and it is what we have repeatedly set forth in this journal ever before Dr. HART's war against this system, which involves an unnecessarily high military expenditure, while the sanitation of this precious dependency of the Crown receives inefficient consideration. We have to express a regret however that Dr. HART, in conducting his war in a great and noble cause should have made use of weapons to wound the feelings of our brethren of an excellent service. While then we absolve Dr. HART of any wilful intent to offend or reflect upon the I. M. Service, his utterances are highly uncomplimentary and damaging to the members of that Service, which has had two alternatives left to it, viz:—"to admit the impeachment by silence, or to emphatically declare against it." It has, we are glad to find, chosen the latter and the wiser alternative and we applaud its spirited defence of its honor, capacity, and intelligence.

However, although the members of the South Indian Branch of the British Medical Association have done all they can, and perhaps all that can be done to marshal all available facts which redound to the credit of the I. M. S. they have in no way disproved the necessity for a much improved sanitary organization in this country. Those present at the special Branch meeting were studiously careful—and this was but natural and to be expected—to make the best possible case but for themselves; and yet in regard to sanitary work in India the sum and substance of all their addresses appears to be:—"well the Indian Medical Service has done all that could be done under prevailing conditions and circumstances; there is no doubt vast room for improvement; but there are many handicapping influences against more marked progression." Indeed Surgeon Lieutenant Colonel W. G. King, who is the Sanitary Commissioner of Madras and, if we mistake not, admittedly the best sanitary authority of that Presidency, said in his address, which was the most important and statistical of all addresses made at the special meeting, "that our sanitary methods, and more especially our sanitary organization demand urgent reform in this country. No one will be more disposed to admit than myself. In this I am at one with Dr. HART." It is for the purpose of bringing about this urgent reform that Dr. HART is strenuously labouring; and for the purpose of getting the Government of the country to recognize that (to use the words of Dr. King) "When compared with its efforts towards organization in other directions, it has failed to give sanitation that full place in its administration, which the public of the present day rightfully demands. If recognizing more fully the importance of sanitation, it would devote a better proportion of existing funds to sanitary organization." Then, we would venture to say, we exactly Dr. HART's view. We vision what the Indian Service is looking most after, and what it needs most for sanitary reform; and what is, of course, the object of the

His wife said he was looking pale, and I was giving him 100 grains, and he was turned very pale.

Upon examining him on the next morning I became convinced that the vital forces had misdirected the remedies and that a miseria of retro-absorptions had resulted. I then wrote out the following prescription:—

Transaceticamphtholamine,
Sodium chloroparacetamidophosphonate,
Orthoamidophenylbenzoic anhydride,
Amidocetoparaphenethiline ... aa ʒj.

M. Sig.: A teaspoonful every hour.

When the wife presented the prescription to the druggist he instantly dropped dead! The patient is up and about, but something is wrong with his Broca's convolution—he mutters in a multi-syllable lingo that is intelligible only to modern pharmaceutical chemists. I am in hiding where the spiral melody of the woodbine blends with that twine with ever sweet, low, soothing, murmurous quadrisyllabic rhythmic runs of the gentle polygonum punctatum.

TEMPERANCE IN RELATION TO THE MORAL AND PHYSICAL HEALTH OF BRITISH SOLDIERS IN INDIA.

The *British Medical Journal* says:—The remarkable influence of the Army Temperance Society India in improving the physical and moral health of the soldiers is brought out very forcibly in the statistics for 1894-95, collected by the Secretary from Adjutants-General and officers commanding corps in India.

Trials by Court-Martial.—Convictions of abstainers, 94; of non-abstainers, 2,181. The number of abstainers having been 20,875, and of non-abstainers, 49,758, the convictions were therefore per 1,000 among the abstainers, 4.54, among non-abstainers 42.92, or nearly ten times as many convictions per 1,000 of the drinkers as of the non-drinkers.

Number Summarily Punished for Insubordination.—Among abstainers, 69, or 48.8 per 1,000, as against 4,610, or of non-abstainers.

Convictions for Minor Offences.—In the three months ending March 31st, 1895, the entries in twenty-six corps among abstainers 23.2 per 1,000; among non-abstainers 99.7 per 1,000. General DANDRIDGE, in recommending separate temperance canteen tents on the line of march, stated that one regiment he inspected in 1885 at Umballa had 175 courts martial, with £100 fines for drunkenness, in one year; next year 37, with a proportionate decrease in the fines. This good effect, added the General, was the result of upwards of 400 of the men having joined the temperance societies.

Health.—In these twenty-six corps during the six months ending March 31st, 1895, the admissions into hospital per cent. were: of abstainers, 6.6; of non-abstainers, 12. We need hardly point to the obvious moral of the great fineness and efficiency values of temperate soldiers.

THE CLIMATE OF CALCUTTA.

WHILE with the need and urgent demand for sanitary science, attention has been closely paid to many of the minor details and immense effort made to control, if possible, the conditions under which diseases spring up, do their deadly work and disappear, the meteorologist has unfortunately been ignored in many instances, and the salient points forgotten that climate exerts a *ponderose* influence on all things living, whether animal or vegetable, and that it is to climatology we must look for the solution of the mysteries that affecting humidity, rainfall, sunshine, winds and temperature, materially influence the animal, vegetable and mineral kingdoms, each of which, though apparently separate, is essential to the other; but nothing can be done save accurate knowledge gleaned except we have correct statistics of both the normal

and the abnormal, to guide us. Taking now account of the fact of the small height above sea level of the generally damp neighborhood, we ought to expect the climate, even though it be some little distance inland, a climate similar to that of a city situated right on the sea coast, and its diurnal range of temperature ought to be much greater than it is. But for some reasons, not clearly understood, Calcutta is precisely the reverse of these requirements that render the Australasian summer so bearable and its hygiene so superior. Calcutta unfortunately does not possess the advantage of the regular diurnal sea and land breeze that its position would entitle it to. We may, however, very shortly learn a great deal of the reasons that influence these changes, and be in a definite position to draw conclusions, as with the assistance of Mr. DOUGLAS APOSTOLIS, the well-known specialist in Indian meteorology, Mr. ELIOT will, on his return from Persia, publish his M.S., dealing with this important subject:

BOMBAY MEDICAL AWARDS.

To stimulate energy and promote zeal among its students, the Grant Medical College is this year offering *substantial* scholarships and prizes as follows:—To undergraduates about to enter the course, 1 Jamkhandi and 2 Cowasji Jehangier scholarships of Rs. 10 per mensem each, tenable for 10 months. To first-year students, five Government scholarships of Rs. 10 each monthly. To second-year students, 1 Reid, 2 Anderson, 1 Farish and 2 Carnac scholarships of Rs. 15, 15, 14 and 13 per mensem respectively. To third-year students, 2 Farish one of Rs. 20 and one of Rs. 15 and 1 Carnac, 1 Reid and 1 Anderson of Rs. 15 per mensem each, together with a MacDonal Prize of Rs. 60 for medicine and a Wellington Gray Medal for anatomy. To fourth-year students, a Carnac, Anderson and Farish scholarship of Rs. 25 per mensem each and a Reid and a Farish scholarship of Rs. 15 monthly, as also a Cursetji and Cowasji Prize of Rs. 60 each; while for those who take their degree of L. M. S. there are 8 prizes and scholarships ranging from Rs. 40 to Rs. 300 each. For the Military Medical Students a special series has also been arranged of awards in the shape of prizes and medals.

NOT SOLDIERS BUT CIVIL ATTENDANTS.

LORD WOLSELEY, the new Field Marshal and Commander-in-Chief of the British Army, while at one of the parades in Dublin, observing that the men of the Medical Staff Corps attending the parade saluted him on his arrival on the ground by "carrying swords," he immediately directed Major-General Montmorency (Viscount Frankfort de Montmorency) to bid the medical officer commanding, to issue the order "return swords," and when giving General Montmorency these instructions, Lord WOLSELEY added that "these men have no right to draw their swords; they are not soldiers, but civil attendants on the sick." This is rather unfortunate for that section of our military brethren who desire to see their professional designation of Dr. or Surgeon completely eclipsed by an out-and-out military designation. Clearly GARNET WOLSELEY does not favor this metamorphosis, and if his will in the matter is to have paramount sway, we fear that a reversion to the old and honored title of "Doctor" will be the reward of our military medical hierarchy.

THE FOUR QUALITIES OF DRUNKENNESS.

WHEN Adam first planted the vine, Satan came and killed a peacock over it, and the vine drank its blood. When the vine grew and put forth its leaves, Satan came again and killed an ape over it, and the vine drank the blood of the ape also. When grapes first formed on the vine he killed a lion over it, and the vine drank up the blood of the lion. When the fruit was fully ripe, Satan came once more and killed a pig over it, and the vine drank this blood also.

... who drinks of the fruit of the vine imbibes
... his qualities. When he first tastes the wine, it
begins to crawl in his limbs, the colour blooms in his face,
and he becomes as gay as a peacock. When the first signs of
drunkenness come upon him, he plays, claps his hands, and
laughs like an ape. When the wine grows stronger within
him, he grows violent like the lion, and challenges every one
else. At last he wallows like a pig in the mire, desiring
only to sleep, and his strength is gone.—*Independent*.

TRUE PHILOSOPHY.

The following is a translation of a passage from Goethe's
Maxims which runs as follows:—

Wouldst shape a noble life? Then cast
No backward glances towards the past;
And though somewhat be lost and gone,
Yet do thou act as one newborn.
What each day needs, that shalt thou ask;
Each day will set its proper task.
Give other's work just share of praise;
Not of thine own the merits raise.
Beware no fellow man thou hate,
And so in God's hands leave thy fate.

HUXLEY says in a footnote to the passage: "I should be
glad to take credit for the close and vigorous English version
but it is my wife's and not mine."

LADY ELLIOTT'S HOSTEL FOR FEMALE MEDICAL STUDENTS.

AMONG the new works of importance under construction in
Calcutta is this new hostel for female students under training
at the Campbell Hospital. The new building, which
is two-storied and is to stand in a walled-in enclosure
to the south of the hospital, is rapidly approaching completion
and is expected to be ready for opening before SIR CHARLES
and LADY ELLIOTT bid farewell to Calcutta. The institution
will supply a much-needed want, and the accommodation
has been devised so as to provide convenient and cheerful
surroundings for the young women who have a severe course
of training to undergo in order to qualify. The work is in
charge of the Executive Engineer, 2nd Calcutta Division, MR.
KRISHNA CHANDRA BANDYAPADHYAY, to whose abilities
and success we have had occasion to refer more than once
recently.—*Indian Engineering*.

HOW THE DANGERS OF CYCLING MAY BE AVOIDED.

DR. GEORGE HERSCHEL says the dangers of cycling may in
great measure be avoided—(1) The use of a low gear; (2) the
upright position in riding; the stooping position prevents proper
expansion of the lungs and interferes with the proper
aeration of the blood; (3) adequate food when riding, and
the avoidance of muscle poisons, such as beef tea—the diges-
tive power of the stomach is inhibited while riding (4) the
avoidance of kola and coca preparations; these, by benumbing
the sense of fatigue, cause more work to be done than is
judicious; (5) on no account should the cyclist continue
riding after he has commenced to feel short of breath, or
when there is the slightest sensation of uneasiness in the
chest.

A SEGREGATION HOSPITAL FOR DARJEELING.

LETTERS have recently appeared in the *Englishman* ex-
pressing the great need there is for a hospital for contagi-
ous diseases in Darjeeling. This station has grown rapidly
during the past few years, and in the summer months has a
European population of about 4,000 souls. The Eden Sani-
tarian cannot accommodate persons suffering from infectious
diseases and such cases, if left in boarding houses or private
families, are sure to spread and may probably assume an epi-
demic form. The absence of such accommodation for the public
is a serious drawback to this popular health resort, and we

trust the Municipal Commissioners will take early steps to
move the Government to supply this need.

THE INDIAN SANITARY DEPARTMENT.

WHILE rejecting the proposals of Dr. W. J. Stimson
at the late Indian Medical Congress (and published on page
222—7 of the Transactions of the Congress) to place the sani-
tary needs of India under the direct executive control of the
Sanitary Commissioner, the Governor-General in Council ad-
mits the force of this Health Officer's remarks, and directs that
if local Governments, Corporations or Administrations, whe-
ther Civil or Military, at any time, require the advice or assis-
tance of the Sanitary Commissioner it should be freely and
promptly given.

His Excellency regrets the absence of proper machinery for
the efficient sanitation of India, and thinks that the sanitary
work done is not at all commensurate with the heavy ex-
penditure incurred; but at the same time feels constrained
to acknowledge that some portion of the executive outturn
has been more than extremely well done, and greatly favors
the idea of encouraging sanitary acquisitions by institut-
ing special diplomas in public health and thus stimulating
the desire for attaining a high standard in hygienic and
bacteriological work, more especially among the Assistant
Surgeons and Hospital Assistants, on whose shoulders devolves
the major portion of the medical needs of this country.
But here, again, considerable thought and care are required,
because the special training of these classes in a thorough
course of hygiene and preventive medicine, together with
the laboratories, medicines and instruments required for
such training, necessarily entails a large expenditure, and
it is not without reason to suspect that after undergoing
such special training, the members of the medical departments
would naturally expect, and possess the right to demand,
a higher rate of salary than they at present obtain. The
Governor-General in Council deploras (H. D. Res. 10-353-44
of 29-9-87) the round-peg-in-square-hole system that allowed
sanitary officers to holiday in hill stations the time they
ought to have spent on inspection duty in the plains, and
relegated to (perhaps) incapable seniors important duties
that ought to have been entrusted to more active and meritori-
ous juniors, and, anxious to mend matters that really are
a scandal to the country, His Excellency calls for opinions
and proposals from the local Governments as to the best
lines on which to create and re-organise the various depart-
ments necessary to efficient hygiene in this land of many
nations and very diverse creeds and customs. So far, we are
at once with His Excellency; but his proposal (clause 9 of
Home Department Proceedings, dated 28-10-95) to amalga-
mate the offices of the Sanitary and Medical Departments
and place them all under the direct control of, and subordinate
to, the head of the Medical Department is not likely, for
many and grave reasons, to meet with general approval, as
it re-establishes, with a vengeance, the very Military hier-
archy that Dr. HART inveighed against, and whose yoke
the civil medical faculty is chafing under: for India
does not possess a purely Civil Medical Service.

ASSISTANT SURGEON JOHN ROWLEY, I. M. B.

WE deeply regret to announce the death of Assistant
Surgeon John Rowley, on 24th October, at Darjeeling, from
blood-poisoning contracted while attending a post-mortem ex-
amination in the Military Hospital at Jalapa, Mr. Rowley
was a smart and talented officer and very popular wherever he
served. He was Civil Surgeon of Kanhangad at the time of
his decease, and had gone on leave to recruit his health at
Darjeeling. He leaves a widow and three children to mourn
his loss, which will also be greatly felt by all who knew him.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

The following names have been added to the list of Members of the Indian Medical Association since the last publication:-

General Havelock Ellis, Assistant Surgeon, I. M. S., Lucknow.
Major General Shalby, C.M.S., Civil Dispensary Baroda.
Dr. Viswanath Phani, C. M. S., General Hospital, Madras.
Arthur B. Leicester, L.M.S., Government Dispensary, Calcutta.

Dr. Ishwar Mahta, C.M.S., Civil Dispensary Chattrapur, Ganjam.

INDIAN MEDICAL PROVIDENT FUND.

The following names are added to those already published as willing to join the Indian Medical Provident Fund.

T. Agarwal Mahta, C.M.S., Chattrapur, Ganjam; Raja Rao Das, C.M.S., Sonapat, Ganjam;

SHORT ITEMS.

"*Tabloids*" of *Salicyls of Magnesium* are recommended by Dr. Brownlow Martin as a local bactericide in the treatment of follicular tonsillitis, aphthae, and soreness. When the salt comes into contact with the mucous surfaces it is decomposed into sulphurous acid, and magnesium. The gentleman mentioned has employed the "tabloids" with special advantage. They are quite palatable, and are not objected to by children.

In Sir Charles Elliott's recent resolution on "Higher Education in Bengal," he pays a well-deserved compliment to our respected confere Dr. Mahendra Lal Sarkar, M.D., C.I.E., for his presidential guidance and care of the "Indian Association for the Cultivation of Science," and remarks that this corporation is doing excellent work and is deserving of cordial encouragement from the Government and the public.

Dr. Lawrie, has in conjunction with his assistant Dr. Jordan, just completed a series of experiments resulting in a complete demonstration of the fact that Laveran's malaria present is nothing but an altered white blood cell, whose vitality is impaired or crippled by malarious fever. Quinine restores the vitality and renders the cell vigorous again.

This General Order, dated 24th March, 1898, has just come to light:—"The bill drawn by Lieutenant Macleod, Barrack Master of Fort William, amounting to forty Bhoos Ruppes, for two wooden legs prepared by Messrs Bruce and Smith for two invalids of His Majesty's 67th Regiment of Foot, is passed by the Governor-General in Council."

This is Professor Huxley's epitaph, written by himself:—
And if there be no meeting past the grave,
If all is darkness, silence, yet 'tis rest.
Be not afraid, ye waiting hearts that weep,
For God still "giveth His beloved sleep."
And if an endless sleep He wills—so best.

The Paris correspondent of the *Times* announces that Dr. Ducloux has been unanimously chosen to succeed the late M. Pasteur as Director of the Pasteur Institute, while Dr. Roux is the sub-Director. These are the appointments that were generally anticipated.

Says the *Londoner Magazine*:—"The question whether physicians should in some cases expedite death, is being seriously asked in professional circles in America, and the response would seem to be that, under certain well-defined conditions, this act is not merely allowable, but quite the duty of medical men."

It is said that the scheme on foot for a new Chemical Laboratory, Department at the Medical College, Calcutta,

is likely to be completed very soon. The new building, which is to be erected on the site of the old one, will be a fine specimen of modern architecture.

We regret to announce the death of Dr. Arthur H. Mansfield, Assistant Surgeon of Calcutta, on 17th March, at the age of 49 years. Sir Rivers Thomson said of him that he was "the best man available in the Medical Medical Service and equal to a Civil Surgeon."

Assistant-Surgeon W. O. Moffitt, I. M. S., of Umballa, has turned out a most proficient Oriental Surgeon. During his brief service of three years he has passed five State Examinations in Indian languages, the last being the Higher proficiency examination in Urdu.

Assistant Surgeon P. A. Whickler, I. M. S., holds the diplomas of L.R.C.P. and S. Edinburgh. His qualifications deserve the special attention of the Office of the Surgeon-General with the Government of India for employment in the Civil Department.

Dr. Gilbert Park, M.D., L.R.C.P., has settled in practice in Calcutta as Dr. S. W. Chatterjee's assistant. He comes to us with a good reputation as an ophthalmic surgeon. We heartily welcome Dr. Park and wish him much success.

Emeritus-Professor John Struthers, lately M.D., Professor of Anatomy at Aberdeen, but originally of Edinburgh, has been elected President of the Royal College of Surgeons of Edinburgh.

Sir Henry Thompson was recently left a legacy of £10,000 by a patient. The friends of the deceased are, it is said, taking steps to have the will of the testator declared null and void.

The *Omaha World-Herald* says that the City Physician and Coroner of Pender, Nebraska, is a woman, who was elected unanimously last autumn after she had been but six months practicing in the town.

Mrs. M. F. Neale, a daughter of the late Dr. E. Ruffery, of the Chandney Hospital, has been appointed to the female branch of that hospital. Mrs. Neale received her training on the Dufferin Fund at the Calcutta Medical College.

Assistant Surgeon Frank Bradley I. M. S. Civil Surgeon, Tiddim, Burma, has passed the State examination in the Chin language, and has received an honorarium of one thousand rupees for the same.

Sir William Mackenzie, K.C.S., whose death is reported, entered the Madras Medical Department in 1855, and served during the Mutiny as Senior and Field Surgeon with the Central Indian Field Force under Sir Hugh Ross.

The western block of the Standard Life Office Buildings, Dalhousie Square, Calcutta, having been completed, the office of the Company has just been removed to the new building.

The "Sequel" Universal Cure Company, whose operations were to ruin all the doctors in the country, itself has fallen in grief, and is now in liquidation.

A Crown's Jury at England once brought in a verdict that "a three months' old child was found dead, and there was no satisfactory evidence that it had been murdered."

Thomas Edin, M.D., F.R.C.S., the distinguished Edinburgh surgeon, died at Edinburgh on the 14th February, at the age of 74.

OUR LONDON LETTER.

(From our own Correspondent.)

PROFESSOR ANDERSON STUART (University of Sydney) provided a patient, who had lost his voice (larynx ?) with an artificial larynx which is a singular success, the changing of certain rods contained in the instrument making the voice express, tender or hoarse, at will.

While enquiring from Leigh to London, the women's part of the R. B. team caught fire. The stewardess, EDITH GARDNER LAMBERT, of Forest-gate, Essex, rushed to their rescue and saved many lives; but as she was going to save a child, she perished in the flames.

The late Mrs. W. W. was the wife of a dwarf (Morgan), who was 25 inches high (and she shorter still) has been reported of being mother and babies are doing well.

Dr. WIGHT, the Police Surgeon of Holborn (London) who is charged with saving the death of a woman named FLETCHER by extensive laceration during forceps delivery, has been committed to the next Court without a witness stating that he was intoxicated while performing the necessary operation, Dr. Wight replied that as he was suffering from the sequelae of influenza, he had taken a large dose of potassium bromide. He has been admitted to bail, on two securities of £500 each.

The heat in London during the last week in September has been quite phenomenal. In the sun the thermometers have registered over 100°F. and on one occasion 120°F. and in the shade from 82 to 85°F. Numerous cases of sunstroke are reported. Some of them serious.

Surgeon-General Sir Thomas Layton, Surgeon to the

Quisp, and Professor of Military Surgery at Netley Hospital died suddenly at Swinage, Dorset on 1st October 1896. The French military expedition in Madagascar teaches some salutary lessons on malarial fever. As the engineers and sappers, who did a deal of road-making, suffered most severely when turning up the earth, and there are said to be over 3,000 invalids in various station-hospitals, while the homeward bound transports are crowded with sick. Scarlet fever is rife amongst us, and the fever hospitals are quite full. Several churches in North London have been entered. Organization is still the watchword chiefly of the Medical Practitioners' Association. A medical contemporary remarks that he does not see why we should support Lock Hospitals, while prostitutes lived in luxury; perhaps however, he might as sagaciously have added: "while gay women went freely about the streets distributing their venereal complaints broadcast." To say the least his arguments do not bear out medical experience in the prophylaxis of venereal diseases, and he ignores the facts that enforced segregation, with the licensing of houses of ill fame has done something in garrison towns, at all events, to lessen syphilis and gonorrhoea, &c.

T. LAUDOR BRUNTON, M.D., F.R.S., the talented Pharmacologist, has been appointed full physician to St. Bartholomew's Hospital.

DR. WILLIAM HICKMAN has committed *felix de se* by swallowing prussic acid. Dr. F. M. WRIGHT ROTTES (M.D.) met his death through attempting to enter a train, while in motion. Saline infusions are much under discussion in medical circles, their exact therapeutic value is still "sub lite." At a meeting of the French Medical Congress anti-cancerous serotherapy has been thoroughly gone into by Drs. BOUNET and G. FERRE. BOUNET says: The injections were not painful and rarely gave rise to abscess; but no cures have as yet been effected. Summing up: the injections often improve the general state, diminish pain and hemorrhage, and are devoid of danger. Dr. G. FERRE employed a serum from inoculated monkeys, treating 15 cases, all of which were in a serious condition. Dose employed was 4 c.c.; general condition improved; capillary hemorrhage lessened, pain abated, tumefaction of size of swelling was diminished.

We regret to announce the death of the Ophthalmic Specialist, Mr. FRANK HODGES, F.R.C.S., Edin. and M.R.C.S., Eng. who hanged himself at Leicester, while in a state of mental aberration.

The medical vacations are now in full swing, the sun heat being from 80°F upwards, in the shade. NABIULLA KHAN has left us for gay Paris, taking his body-physician, Dr. LILIAN HAMILTON with him. Sir HUGH BEEVOY found thyroid gland beneficial in a case of alopecia. Sir E. C. BUCK, Secretary, Indian Department of Argiculture, states definitely that during his stay at Sorrento that asthma was, and can be, cured by residing in the neighbourhood of orange lemon groves. It is proposed to build a much-needed hospital in South London near about Camberwell. Smallpox has visited us frequently during August and September, 520 variolous patients being now under treatment in hospitals of the Metropolitan Asylums Board. The "Drink Question" has again been discussed ad libitum in lengthy and erudite reports, but as the

harm of temperance is spreading fast, surely amongst the masses of the British population, the subject is ripe for legislation in that respect is responsible, as Sir DOCKRILL and TUCK long since stated for much efficiency, and for about 60 per cent. of the patients in the system. The Whitechapel guardians have been permitted to arrange for the payment of fixed fees to medical men for out-door attendance on the poor of their districts. The University College entertained 5,000 visitors (in Gower Street) who were received by Sir JOHN ERIC BAILEY, while the string band of the Royal Engineers furnished the music. Dr. MARAGLIANO's patients (pulmonary tuberculosis) have shown marked improvement from injections of anti-tuberculous serum. A bride of only 14 days has put a period to her existence by taking paraffin in repeated small doses. Professor LANK-TROTTER, of Netley has been reappointed as Professor of Military Hygiene for another term. The new buildings of the Royal Free Hospital just completed at a cost of £30,000 have been opened by H. R. H. the Prince and Princess of Wales. Helium and Argon, the two new chemical elements, are engaging the further attentions of Professor RAMSAY, who promises us at least two more fresh elements. Those mentioned above are monatomic? Density of Helium is 2.2, and it is the most insoluble gas yet known. The experiments of Drs. STUART, J. C. MARTIN and TIDSWELL on the poison produced by the femoral glands of the ornithorhynchus paradoxus show that (1) it is a proteid poison like that of other Australian snakes, and does not contain nucleo-albumen. (2) It is in June that the spur of the Platypus gives rise to its most virulent symptoms. Coagulation of the blood follows its introduction into the circulation; and capillary hemorrhage and oedema, when applied locally. Dr. H. D. LITTLEJOHN, M.D. Edinburgh (late President R.O.S.E.) is to be knighted. H. R. H. the Prince of Wales has accepted the Chancellorship of the University of Wales *vic* LORD ABERDEEN, deceased, and has recently laid the foundation of the extension of the Royal Medical Benevolent College, Epsom.

Potassium permanganate is still being tested in opium poisoning. Dr. ERNEST HART has published some papers on waterborne typhoid, from which much useful information may be gleaned by the progressive and studious physician, having in view the numerous fatalities occurring through out India and South Africa due to enteric fever. Sir R. W. RICHARDSON calls attention in *The Aesclepiad* to the increase of deaths from anaesthetics. News from America of the beneficial effects of antisyphilitic serum is confirmed in the clinique of Mr. COTTELL in London. Mr. JOHN LENTAGUE succeeds the late Sir GEORGE PORTER on the Council of the R.C.S.I.

The King of Italy has conferred the order of St. Maurice and St. Lazarus on Dr. VINTAS, Senior Physician to the French Hospital and Italian Embassy in London. Sir JOSEPH FAYER, F.R.C.S., F.R.S., and Sir GURAN HARTON head the Committee in proposing a memorial to Professor HUXLEY in connection with Charing Cross Hospital. Sir PHILIP STOKELY has been appointed Surgeon to the Queen-Empress in Ireland. Sir JOSEPH LARSEN, F.R.C., has been presented with his portrait painted by J. R. LORIMER, A. R. S. A., on the occasion of his retirement.

from the King's College Hospital. Dr. FINLAYSON (1889-90) has reported a case of bilharzia haematologica studied by Dr. E. JONES in a man who served in the Sudan and was admitted to the Western Infirmary with haematuria. The doctor showed microphotographs of this parasite in various stages of development from the egg hatched in pure water. No embryos were found in the urine as described by some authorities. He added that medical Egyptologists recognised the endemic haematitis described in the "Ebers papyrus," page 16, the date of which M. S. was about 1550 B. C. What about the anchylostoma duodenale, so common among the Fellahs?

Knighthood has been conferred on Mr. THORNTON STOKER and Dr. CHRISTOPHER NIXON (Dublin). In a Limerick Convent three persons died of irritant poisoning, which Sir CHARLES CAMERON has traced to a custard they had eaten.

A Parliamentary report tells us that Mr. JANEZ HOGG has been granted a Civil List pension of £75 in consideration of his scientific medical services. Dr. BERNARD O'CONNOR has failed to attain to Mr. CHAMBERLAIN'S Birmingham seat. Dr. KITASATO'S service to medical science has been recognised by Japan, the land which gives him birth, by the Government voting him money to be expended on his laboratory work.

The Duchess of Portland presented the prizes at the annual meeting of the London School of Medicine for women, when an address was read by the Dean, Mrs. GARRETT ANDERSON, M.D.

During last week there have been nine deaths from the explosions of cheap oil lamps. According to the report now issued for 1894 by the Inspector of Inebriate Retreats, there are 9 of these asylums doing excellent work, but seclusion in these Retreats should be made compulsory, not voluntary.

Brigade-Surgeon Lieutenant-Colonel E. J. FAIRLAND, of Netley, reports a case of Raynaud's disease following malaria acquired in Hong-Kong and treated with opium and quinine. We mention with the deepest regret the death of Sir JOHN TOMES, F.R.C.S., F.R.S., L.D.S. who has done so much for Dental Literature.

A new and apparently successful method of combating opium poisoning is by injections (subcutaneous) of strong coffee. The latest craze among the men and women of the Upper Ten is tattooing. A great loss is sustained by the profession by the death of JOHN SYR BRISTOWE, M.D., F.R.C.P., F.R.S. the talented author of a treatise on medicine, still a leading text-book among medical students and practitioners. It is proposed to treat infectious fevers by first wrapping the patient in sheets soaked in milk, and then giving them a warm bath.

H. I. H. the Emperor of Germany promises £500 towards a memorial to the renowned physiologist HELMHOLTZ. The Milner Fothergill gold medal has been awarded to Dr. EDMUND SMITH for his essay on "The Digestive Ferments."

The result of injections of anti-streptococci serum in cases of puerperal septicæmia, peritonitis, &c., have given marked success, if we are to believe continental authorities. Dr. KITASATO is, we are told, working out an anti-leprosy serum, the details of which have not yet been published in full. Leprosy is decidedly on the increase in Cape Colony.

Current Medical Literature.

MEDICINE.

A new Treatment of Seminal Weakness, with especial reference to Sexual Neurasthenia.

DR. ALFRED WIENER uses for this trouble, a special instrument devised by himself, which he has termed the *psychrophore*. The cases which are most likely to benefit from this method of treatment present the following symptoms:—Prostatic portion of urethra extremely sensitive and hyperæsthetic; there are frequent seminal emissions, causing exhaustion, more or less; erections are frequent, of short duration and imperfect. The sexual desire is very much diminished or absent altogether. The patient masturbates excessively together with these local symptoms. The patient usually complains of neurasthenia, depression of spirits, inability to walk, or to concentrate his mind upon anything, listlessness, insomnia &c. The *psychrophore* consists of a central bulbous piece for insertion into the rectum, having a concavity to fit into the prostatic portion of the urethra and two arms, for fitting on a cold waterbag to one end and an egress tube to the other. These parts unite to form a T-shaped instrument. The rectal portion is introduced and a stream of ice-cold water passes through and leaves the prostatic portion of the urethra, at an equable temperature being maintained the while. This application should be made for 10 to 15 minutes daily.

Twelve cases are cited, presenting in common the symptoms above enumerated. Some having in addition organic stricture and from a state of sexual impotence, and exhaustion have been so benefited by the treatment as to quite regain their wonted state of health, in from 3 to 6 weeks, which has been thereafter maintained.—Bromides are useful in the early stage of application of the *psychrophore*, to overcome the sensitive hyperæsthesia of the prostatic urethra. The author discountenances *urethral* psychrophorisation as being more difficult and painful to apply and less efficient in results.

The use of Aconite in Diseases of Children.

M. JULES CORNBY regards aconite of value in those diseases of childhood which are characterized by a *spasmodic* element. As in asthma, pertussis, laryngismus, stridulous palpitations, convulsions, &c. In spasmodic affections of the respiratory passages, J. SIMON finds a combination of aconite and belladonna useful. In diseases of the heart, to mitigate the effects of digitalis, aconite is often associated with it. (BLACHE). It may also be combined with opium for neuralgia and quinine for malaria fever. If the respiration is embarrassed, or the child depressed, prostrated and somnolent and the heart weakened, aconite, owing to its depressant action, is contra-indicated, e.g., in capillary bronchitis, pericarditis, valvular affections, diphtheria, typhoid, &c. In pneumonia, scarlet fever and variola, aconite often produces excellent results.

(2). Regarding the mode of administration, preparations made from the root of the wild plant are the best. Instance a preparation known as *alcoholature*, made by macerating for 10 days 1 part of the fresh roots in 1 part of alcohol at 80°. A syrup is sometimes made from this by combining 1 part of the *alcoholature* with 10 parts of syrup. Some French physicians use the *tinctoria* in preference to all other preparations.

MR. CORNBY condemns the use of *aconites* in children as being extremely active and very difficult to control. Small

case of influenza pneumonia was probably in large measure at least.

PREVENTION.

Hayes' conclusions apply to the above subject. He made a series of inoculations and cultivation experiments which he divided into three groups:—(1) Animals inoculated with the blood of influenza patients: 4 out of 7 rabbits previously injected with quinine were protected from the disease in various degrees. (2) Animals inoculated with PRIZREN'S bacillus. In 4 out of 4 rabbits previously inoculated with quinine no disease appeared, while 2 of the control animals took ill and died. In one case there was latent tuberculosis which at once became active as soon as the influenza caused diminished resistance in the animal. (3) Cultivations made from the blood of influenza patients and rabbits infected with influenza. The first of these cultivations gave negative results, in the second set, PRIZREN'S bacillus was revealed in 1 out of 3 rabbits previously protected with quinine and in 2 out of 3 not so protected. The author concludes that quinine is a good prophylactic, and to some extent a preventive of influenza. He gives 1 to 1.25 gramme on the first two days 0.8 gramme on the third, &c., and so on. Hypodermic injections have the advantage of not upsetting the stomach and of reaching the circulation more rapidly and directly. He gives details of 3 very severe cases of influenza and pneumonia so treated, with 2 recoveries.—R. M. J.

The Physical Signs of Abdominal Disease.

IN HAYES' lectures by LION is considered the effects of compression or as he terms it "corset disease." He describes three chief deformities. The first is a supra-hepatic condition with diminution of the antero-posterior diameter and the lower ribs being displaced outwards the liver is displaced downwards while the stomach assuming an almost vertical position, makes the transverse colon become V-shaped. In the second variety there is hepatic constriction, the liver increases in vertical extent and presses the pylorus and duodenum against the vertebral column, the result is dilatation of the stomach with perhaps hour-glass constriction. The third variety is considered as the most important. It is the sub-hepatic in the compression taking place at the level of the last rib and the lower margin of the liver, there is a displacement upwards of the liver and tension of the diaphragm causing dyspnea and palpitation. The transverse colon is also displaced, and constipation is caused, especially as the dyspnea prevents the patient leading an active life.

The Treatment of Malarial Hematuria.

Drs. H. A. HARR and WILMER KAUBEN present the results of a collective investigation, based upon one hundred and seven replies to questions which were sent out, the area covered being that having a death-rate from malaria of 70 per cent. or over. Thirty-two remedies were used: the first six were calomel, tincture of ferric chloride, arsenic, ergot, turpentine, and sodium hypophosphite, each remedy being used by ten or more physicians. Calomel is used in from 5 to 50-grain doses, and seems to be most in favor. Tincture of ferric chloride is used either alone or combined with arsenous acid in small doses of quinine. Arsenic is recommended from 1 to 5-drop doses (Powder's solution); the only caution stated is that the urine shall be clear. Sodium hypophosphite may be given in from 30 to 40 grains every three hours, after thorough purgation with calomel. Ergot is regarded as a haemostatic. Turpentine, in capsules, two drops every three hours until the urine clears, and a turpentine liniment in the lumbar region, may arrest renal hemorrhage.—Therapeutic Gazette.

Dr. CHAS. C. COLEMAN, of New York, has given a consideration of pain that arises from ulcers of the leg, and a return to a healthy condition of a patient who has received the proper treatment, whether it be surgical. For aetiological purposes ulcers of the leg may be divided by the author according to their appearance, as venous, traumatic, traumatic, etc. In traumatic cases, the patient is placed foremost thorough washing with soap and water and good scrubbing with a stiff bristle hair-brush. If the ulcer be inflamed, irritable, or painful anæsthesia may be required for this and subsequent steps. The next step is a thorough cleaning out of all soft granulations and the base of the ulcer with a sharp curette. The edges of the ulcer are freed from their attachment, and in many cases with a curved sharp bistoury he makes the circumference at intervals of about one-quarter of an inch. If much hemorrhage follows, a pad of gauze wrung out of a two per cent. solution of carbolic acid is placed over the wound and a firm compression bandage from the toes to the knee applied, the wound having previously been thoroughly cleansed with the carbolic solution. The dressing, when used, is allowed to remain for twenty-four or forty-eight hours after which he considers the ulcer to have become a simple one and amenable to treatment as follows: No further lotion is used. The wound is wiped off with dry cotton, and and completely covering it over he places strips of diachylon plaster to protect the ulcer. Over the surgeon's plaster he applies a pad of sterilized gauze held in place by strips of rubber adhesive plaster or often simply by bandages. He then uses a firm muslin from the toes to the knee, making a bandage of equable compression. Bandaging should be carefully done. Sometimes he uses two bandages three inches wide and eight yards long. This bandage is not removed unless the discharge comes through, or the leg becomes painful, or the bandage gets loose. When he redresses the ulcer he again uses simple dry absorbent cotton to cleanse the wound and proceeds as before. Often after two to three days the bandage may remain five or seven days without being disturbed. In some cases a thin scum forms on the ulcer, which must be removed by going over the surface lightly with a curette. When this treatment is adopted in ordinary cases about three weeks will suffice for an ulcer of even a dozen years standing. In extraordinary cases as much as six weeks may be necessary.

Replantation and Transplantation of Teeth.

AN interesting paper on this subject was read by Dr. BENEDICT at a meeting of the Army Medical Staff at Edin. Fest. He said that AMBROSE PARR was the first who performed replantation of teeth, and was followed by SURROTT and POMARRET the latter of whom recorded a case, where a tooth which had been extracted by mistake was replaced and eventually adhered. WELCH has performed eighty replantations among which two have failed, and he also proved by experiments on dogs that absolute integrity of the periodontum is one of the most important conditions of a permanent adhesion of the tooth. By replantation Dr. BENEDICT found an operation by which a tooth is inserted into living tissue, with which it must enter into intimate contact. He distinguishes between replantation and transplantation, the latter consisting in the transplanting of a tooth from one person to another. In his experiments he used a tooth from a dog, which he showed to be a dog's tooth, and with a slightly granulated, the tooth being a specimen of a tooth. The wound was closed with a

...and the tooth was removed from the socket. The tooth, which was to be replanted, was preserved in alcohol. After two days a reddish head was to be seen, and the tooth could be moved backwards and forwards in the gum, it was usually fixed. According to Dr. BENEDICT, the indications for the above operation are loosening of the tooth, caries, and inflammation of the periosteum surrounding the root. A tooth which has been removed from its socket by mistake on the part of the dentist or by violence should be replanted. In the case of toothache from caries where it is impossible to apply any remedy to the painful place the tooth may be extracted, filled with stopping after removal, and then replaced. Dr. BENEDICT proposes that the tooth should be carefully extracted, avoiding injury to the socket of the surrounding gum, for a fracture of the alveolus would render subsequent union impossible. The root is then to be trimmed smooth as it is rough and eroded, and the tooth is to be replaced after the removal of the pulp and the disinfection of both tooth and alveolus with sublimate. The operation is followed by no great pain and by only a trifling inflammation of the gum.—*Lancet*.

Ophthalmia Neonatorum.

THE statistics given by HAUSMAN of the inmates of blind asylums made blind by this disease was: In Copenhagen, 8 per cent.; Berlin, 20 per cent.; Vienna 30 per cent.; and in Paris, among 208 blind, young subjects, 45 per cent. In 1879 among the young persons admitted to the blind institutions of Germany and Austria, 33 per cent. had been made blind by this disease.

In different countries the variation was from 20 per cent. to 79 per cent. In Philadelphia, in 1871, out of 167 inmates of the blind asylum, about 20 per cent. had been admitted for this cause.

Since prophylactic measures have been resorted to in lying-in hospitals, it had the effect of reducing this number from 12 per cent. to 3 per cent. in Halle, and in Leipzig, where CREDE used his own method, the cases fell from 75 per cent. to 0.5 per cent. The treatment consisted in putting a single drop of a 2 per cent. solution (gr. x to ʒj of water) of silver nitrate between the lids of each eye. Practically the same results have obtained in the United States. In the 158 inmates of the Berkeley Institute, California, of 36 cases of binocular blindness 25 per cent. was caused by blennorrhoea neonatorum.

Hayes found that while from 1870 to 1880 the population of the United States had increased 80 per cent. the number of cases had increased 140 per cent.; the number decreasing from the east to the west, but increasing from the north to the south.—*Canad. Pract.*

Acute Genorrhoeal Rheumatism.

DR. HOWARD LILIENFELD has a preference for oil of wintergreen and sodium bicarbonate, with considerable attention to the alkalies in the treatment of this disease. The diseased joint should at once be put at rest upon a splint of such proportions that as much comfort as possible may be obtained. Gentle compression over a dressing of ichthyol ointment, twenty to fifty per cent. or other mercurial ointment, or over an antiseptic wet dressing, should be applied by bandage. If the disease seems to be manageable, gentle massage is valuable during convalescence; but if ankylosis is inevitable, it should be resisted by perfect fixation in plaster of Paris. The indications for the diet are: meat, eggs, milk and its preparations, butter, whole wheat and easily digested food, should be taken upon the patient every two hours or oftener, and at intervals should be kept at all nourishment taken.—*Am. J. Med. Sci.*

Stomach Surgery.

Gastroctomy.—(1) The smallest amount (in the first case) of antiseptic possible should be used; (2) all antiseptics should be avoided in the stomach cavity; (3) the extra-peritoneal method of resection should be adopted, the posterior part of the ring of stomach is surrounded by gauze, and the situation of the remaining stomach should be permanently extra-peritoneal, the anterior wall of the stomach is covered in by a flap of skin; (4) the patient should be fed early by the mouth.—*LANGEHAUS*.

In Prolaps of the Rectum.—Sometimes much relief is obtained by injecting, before going to the chair, from ʒiij. to ʒviij. of warm water, and afterward an ounce of cold water, and allowing it to remain.—*KIRBY*.

OBSTETRICS AND GYNECOLOGY.

Unruptured Hymen at full term of Pregnancy.

EDWIN T. ENOB, M.D., New York, writes to the *Lancet*:—The following case, although not by any means unique, I think, sufficiently rare to make it worthy of record. All have heard and read of such, but in an experience of something like 4,000 labors, extending over a good many years, I have never personally met with such a one before.

The patient was a woman about forty-two years of age, who had been married ten years. Her husband, unmarried previously, was a very corpulent man, apparently of the age of

forty-five. On examination I diagnosed the existence of a perfect hyaline, which admitted the passage of the index finger without difficulty, but not of the first and second fingers without risk of rupture. The presentation was normal, the head being in the best position; the membranes were intact. The labor was very slow. When the dilatation of the os was practically complete I ruptured the membranes, and twelve hours later delivered under chloroform, administered by my friend, Dr. BAWEN. The hymen was ruptured in the application of the forceps, but there was no perineal laceration and the child, a well-developed female, was living. The total duration of the labor was forty-five hours. Both mother and infant are doing well.

One Hundred and Thirty-three Cases of Placenta Prævia.

BOSS collected these cases, which occurred between April 1884 and April 1894, in two institutions in Breslau. In one of the hospitals the proportion of placenta prævia to normal labor was 1 in 216, in the other 1 in 42—a remarkable difference. In 27.9 per cent. the placenta was central, in 61.6 lateral, in 10.5 marginal. The percentages of presentations were as follows: Head 66.2, breech 1.8, footling 8, and transverse 24. Of the total 138 mothers, 8 died; 5 from direct effect of loss of blood, and 3 from fever or exhaustion after the first week. Twenty-seven per cent. of the children were born alive. As for management, the tampon, with expectant treatment, was applied in 7 cases, rupture of the membranes with forceps in 9, forced labor in 1, and combined version in 115; in this latter category all the maternal deaths occurred. The cases, however in which combined version was employed, were all severe. One patient died from air in the veins nine hours after labor.—*Brit. Med. Jour.*

The use of Pelvimetry in Gynecology.

GEORGE W. DOBBIN says:—Pelvimetry is not appreciated by the gynecologist as by the obstetrician. KALY, who first called attention to the subject, described a very simple method by which the true conjugate could be ascertained with a fair amount of accuracy. The patient lies in the dorsal position, the legs flexed slightly on the thighs, and the latter on the abdomen. The operator faces her on her left side, and "with the palmar surface of the open left hand directed downward, he makes, with graduated pressure, deep palpation in the median line directly over the superior straight, feeling for the promontory of the sacrum with the tips of the fingers." These should be allowed to glide to a point immediately above the promontory and remain there: the posterior point of the antero-posterior diameter is thus fixed; the middle finger of the right hand is now passed behind the symphysis pubis over its most salient point and then turned up, and a mark made with the finger nail on the palm of the left hand. The distance from this mark to the tip of the middle finger of the left hand gives the conjugate diameter. The chief source of error in this proceeding is from pressing against the promontory instead of allowing the fingers to rest just above it.—*Amer. Jour. of Obstet.*

Hyperemesis Gravidarum: Difficulty in Inducing Abortion.

CHARPENTIER observed uncontrollable vomiting, from the beginning of pregnancy, in a secondipara, aged 28. At the third month the state of the patient was so grave that it was necessary to provoke abortion. A rubber bougie was passed into the uterus, and another on the following day, then a dilating bag, then Hagar's dilators from the smallest to the largest. Lastly, nitrate of silver was applied to the

uterine cavity. The same day the operation was performed. The patient recovered. She was hysterical, and CHARPENTIER believes that hysteria is often the cause of uncontrollable vomiting in pregnancy.—*Brit. Med. Jour.*

Latent Gonorrhoea in Women.

DR. W. E. PRYOR believes that in a majority of prostitutes and in almost all women who have had gonorrhoea, there may spring up, from irritation of any kind, a discharge containing gonococci and differing only in degree from that due to recent infection.

Microscopic examination of the discharge collected from the cervix, urethra, and the vagina, of a large number of patients, many of whom complained of no local discomfort at the time, led to the opinion that a purulent discharge from the genitals rarely existed without gonococci being present in it or in the tissues producing it. The gonococcus is frequently present when there is no perceptible discharge of any kind, and while the vaginal discharge is rarely free from other pus-producing organisms and may even appear to contain no gonococci, the scrapings by a Volkmann's spoon will usually shew the tissues of the cervix to contain gonococci generally without other micrococci. The author draws the evident conclusion that one is not able by simple inspection to declare a patient free from gonorrhoea.

The experience of the author is that, after a woman is infected, she rarely is completely cured of this disease. This is due to two causes: she will not persevere in treatment after the annoying symptoms disappear, and when the cervical racemose glands are invaded, it is almost impossible to eradicate the disease from them. The stronger preparations of iodine seems to be more effective for this purpose than other remedies.—*Jour. Cut. and Genito. Uria. Dis.*

Vaginal Hysterectomy on a Large Scale.

LANDAU has removed the uterus through the vagina 277 times during the past nine years; 13, or not quite 5 per cent of the patients died. In 112 of these cases the disease was cancer or sarcoma of the uterus; 8, or a little over 7 per cent, died; 1 sank from diabetic coma, 1 from obstruction, and 1 died from sepsis due to abortion, which complicated the disease and the operation. In 56 of the series the uterus was removed for fibroid; in many instances the tumour reached as high as the umbilicus; 4, or over 7 per cent, died, 1 sinking from failure of the heart's action on the twenty-second day, and another from chronic nephritis on the nineteenth day; 109 patients underwent the operation for bilateral chronic septic or inflammatory disease of the appendages; 1, or less than 1 per cent, died, the fatal end being due to diffuse septic peritonitis; 1 suffers yet from a small entero vaginal fistula. The remaining 107 have all been restored, in most cases after years of discomfort or pain to perfect health. LANDAU adds 2 cases of vaginal hysterectomy for acute puerperal sepsis with multiple collections of pus in the pelvis; 1 of the 2 died of purulent peritonitis. LANDAU did not operate in the same manner in all the 277 operations; sometimes he removed the uterus entire, in other cases he bisected it vertically, whilst in some he removed it by morcellation.—*Brit. Med. Jour.*

A Rare Obstetric Anomaly.

M. PEAN, the French surgeon, lately performed a successful operation on a young girl who suffered from incontinence of urine, caused by the presence in her vagina of a super-numerary bladder and urethra. Cases of this description are extremely rare, and where they do occur it is hard still to find them entirely amenable to art.—*Proc. Med. Socy.*

Ichthyoides Fæces.

Treatment as follows:—A ten per cent. ointment of cocaine to be applied and bromides administered internally; at the end of a week the affected parts are to be painted with tincture of iron twice a week; under this treatment the burning and smarting soon diminished and the fissures healed. Next the parts were smeared with Lassar's salicylic paste, and finally tampons were applied soaked in a ten per cent. solution of ichthyol resorcin. In two months the parts assumed a natural appearance, and recovery was complete.—*BRICKE, N. Y. Med. Rec.*

The Maternal Impression Theory.

HARTMAN describes the birth and anatomical structure of a double monster (*cephalothorax copagus*), and notes that the mother was alarmed, when pregnant, by seeing in the forest a newborn fawn shewing a similar monstrosity. She considered that that adventure was the cause of the malformations in her child, and **HARTMAN** seems inclined to support her opinion.—*Brit. Med. Journ.*

—O—

PHYSIOLOGY. PATHOLOGY AND BACTERIOLOGY.

The Maternal and the Fætal Blood at Birth.

As the result of a series of clinical observations, **ELDER** and **HUTCHISON** have found that the blood in the newly-born child is relatively richer in red corpuscles than that of the adult by from 350,000 to 500,000 per c.cm. For a short time after the birth (up to about two days) the red corpuscles seem to increase in number. This is probably due to the fact that the total volume of blood is less, from the fluid lost from the body during this time being in excess of that absorbed. Thus concentration of the blood is produced. After the second day or so the red corpuscles gradually decrease. The number of red corpuscles varies much more than in adults, probably because of greater variations in the total volume of the blood. At birth there are always present a considerable number of nucleated red corpuscles. They vary, however, in number in different cases. About the sixth month of intrauterine life the number of nucleated red cells is very much greater than at birth. They probably decrease in number during the later months of pregnancy, and altogether disappear from the blood a few days after birth. The blood of the newly born child is relatively much richer in hæmoglobin than that of the adult. The mother at parturition is anæmic. In any individual case the blood of the mother is considerably poorer in red corpuscles per c.mm. than that of her child, and it is still more deficient in hæmoglobin. Both the blood of the mother and that of the child contain a longer number of white corpuscles than normal adult blood. The blood of the mother may be quite as rich in white corpuscles as that of the child. The blood of the child contains a distinctly larger proportion of lymphocytes and a distinctly smaller proportion of neutrophile leucocytes than the blood of the adult; the number of eosinophile cells seems to be slightly deficient. At the sixth month this excess of lymphocytes is probably even more marked than at birth; these probably decrease during the later months of pregnancy. After parturition the number of white corpuscles in the blood of the mother (at least when she suckles her child) decreases markedly in a few days.—*Edinburgh Medical Journal.*

The Blood in Syphilis.

In 1889, **SEMOLLA**, after working upon the subject, advanced certain propositions regarding the changes in the blood

produced by syphilis. These were as follows:—1. Constitutional progressive syphilis not treated with mercury causes a diminution of the red corpuscles and of hæmoglobin. 2. If a syphilitic person in whom this diminution is observed is treated with mercury, from the first day of treatment there is an increase of hæmoglobin and of red corpuscles. 3. If, however, the mercurial treatment is continued longer than necessary, so that the mercury loses its specific power, its tonic action will produce a diminution of hæmoglobin and red cells. 4. If mercury is given to a healthy person, there appears to be rapid diminution of hæmoglobin and red cells. **JUSTUS** has lately been investigating the subject, and has recently published his results in the *Wien. Klin. Rund.* Some of them are directly contradictory to **SEMOLLA's** propositions. **JUSTUS** considers:—1. In untreated syphilis the hæmoglobin is more or less diminished, varying with the severity of the disease and its tendency to spontaneous recovery. 2. A sudden diminution of hæmoglobin follows inoculation or injection of a large dose of mercury. 3. The diminution caused by mercury varies according to the severity of the disease and to the condition of nutrition; with injections of mercury, the fall of hæmoglobin can be repeated after several injections. 4. The cure of the syphilitic lesions begins when the fall of hæmoglobin ceases, and is followed by a rise. 5. The sudden fall of hæmoglobin, due to mercurial treatment, is a specific peculiarity of the blood of syphilitic persons only, and does not take place in healthy individuals or in other diseases. 6. This specific reaction of the blood is established at the time when swelling of the gland occurs; it disappears at the time when the existing syphilitic lesions attain the height of their development. **JUSTUS** believes that a specific change occurs in the blood of syphilitic persons, and that this points to a specific means of treatment applicable only to the blood of syphilitic persons. This specific condition of the blood, established by the action of mercury, precedes the affection of other organs; and the disappearance of this specific reaction or the involution of the specific blood change, occurs before retrograde changes appear in other organs. The cure by mercury is in all cases not absolute, but only varies according to the duration of time. The application of **JUSTUS's** statements to diagnosis is this:—In doubtful cases, and in cases of late syphilis with a fresh train of symptoms, a diminution of hæmoglobin, after injection with mercury, is characteristic of syphilis.—*Med. Times and Hosp. Gaz.*

Pathological Anatomy of Progressive Muscular Atrophy.

CRAMER gives a summary of the published cases in an exhaustive paper, and draws the following deductions from the data: (1) Some forms of muscular atrophy which have lasted even for as long as ten years show by our present methods no changes either in the central or in the peripheral nervous system. These forms of muscular atrophy come under the heading of those cases which **HAS** has included under the name of "dystrophy." (2) The atrophies which occur with recognisable spinal lesions present very different clinical pictures. With the same spinal lesion there may be either the symptoms of dystrophy or of spinal muscular atrophy. Even an isolated disease of the cells of the anterior cornu may give rise to the most different clinical signs. Dystrophy may therefore occur with a spinal lesion or the peripheral and central nervous system may remain intact. (3) Cases are to be found intermediate between all forms of muscular atrophy, with and without lesions in the nervous system. (4) The appearances in the muscles are the same whether the central nervous system partake in the disease or not. (5) The pathogenesis of muscular atrophy is still obscure.

Unsanitary and Unhygienic Development.

It is the duty of the medical thought of the day to pay heed to the sources of disease. Overcrowding in cities, child-labor, unsanitary and unsympathetic toll by the mothers, are some of the potent causes of these crimes, and they appeal to the hygienist and to the legislator on the basis of race deterioration and harm to the State.

The absolutely dissolute should be isolated and their labor made productive; first, to prevent the transmission of their pernicious qualities; secondly, to relieve the State of the burden of their maintenance in asylums and reformatories. —H. H. Longsdorf.

A Medical Libel Action.

At the Victoria Courts, Birmingham, on 14th, September Mr. BARNES, acting as Under Sheriff for the county of Stafford, sat with a jury to assess damages in an action for libel, which the defendant had allowed to go by default at the answer.

The case for the plaintiff, Dr. H. SHORE, of Walsall, was that in a letter which was written by the defendant to a local newspaper he had been libelled. The letter was written in reference to an inquest which had been held on the body of CAROLINE JOHNSON, aged 76, the mother of defendant, owing to Dr. SHORE'S refusal to grant a certificate. After hearing the evidence the coroner's jury had returned a verdict of "Death from natural causes." Mr. D. S. JOHNSON, in his letter, complained that "he thought it a cruel injustice to have an inquest forced upon him when such a thing was in his opinion, entirely unnecessary." He further made the following statement, that "at the inquest Dr. SHORE was asked by the coroner what the deceased was supposed to be suffering from when he was called in, to which the doctor made the startling reply: "Fracture of the hip and other injuries."

"Now this is a most wilful untruth, as neither my sister nor I ever expected such a thing. The coroner then asked him what was his opinion as to the cause of death, when he replied: "The mental changes consequent upon old age accelerated by erysipelas....." Now this I find to be absurd. He further remarked that she might possibly have lived another fortnight if erysipelas had not set in, but not longer. Then I ask why I should be put to the outrageous ceremony of an inquest with its attendant and false reports in the evening papers?"

There was a further passage in the letter which the editor struck out, imputing that "the inquest fee of £11s. proved too great a temptation for him, (Dr. SHORE). It was contended that the defendant by his letter imputed to the plaintiff that he had committed wilful and corrupt perjury at the inquest, and that he was ignorant and unfit to perform the duties of a medical practitioner; also that he refused to give a certificate of death in order that he might obtain the inquest fee. Damages to the extent of £100 were claimed. Judgment went by default, and the case was remitted to the Sheriff for the purpose of assessing the damages. At this point the defendant attempted to re-open the case, but was promptly checked by the learned judge, who refused to allow him to speak on other than the question of damages. It was held that the plaintiff need not prove any specific damage, but that any suspicion of the kind indicated upon a professional man was a subject for damages.

The defendant spoke on his own behalf in mitigation of damages, and stated that he would have settled the matter out of court, but that the prosecution insisted upon a publication of the apology, and this he would not consent to allow.

The Under Sheriff came up to the point that it was of this nature upon a medical issue might be the subject of damages, but that it would not do for the jury to estimate the damages at a larger amount than the defendant would pay. He pointed out that the defendant, by persisting in his position that the libel was true after he had allowed judgment to go against him by default, had made the matter most serious, and the jury might, if they thought fit, take this into account.

The jury returned the damage at £10.

The remark of the Under-Sheriff upon returning the verdict that the defendant was a "very lucky man" will be echoed by all the members of the profession. It is difficult enough for medical men to defend their professional honor against the attacks of unprincipled persons, as to do this entails expenditure of time as well as money, but it will be doubly difficult when a jury estimates the damage admittedly sustained (the defendant in this case having attempted no defence) at such a low figure. Dr. SHORE is to be congratulated by all of us on his pluck in bringing this case forward, but we must also sympathize with him on the verdict. We notice that apparently Dr. SHORE was not a member of any defence union. —Brit. Med. Journ.

—10—

THERAPEUTICS AND PHARMACOLOGY.

Serum Therapy of Cancer.

SALVATI and GARTANO give the result of their clinical experience in the treatment of cancer by injection of serum derived from a horse which had been previously inoculated (through the trachea) with an infusion of triturated sarcoma. Five patients suffering from undoubted cancer, mostly relapses after previous operation, were subjected to the treatment. No ill results were observed after injection. The lancinating pains in the majority of cases disappeared completely for a time—after 10 to 20 injections—but as a rule returned again with their previous intensity. Hemorrhage from the ulcerated surface was a frequent occurrence after injection. The tumours were observed to diminish in size in the early part of treatment. Still, notwithstanding the manifest improvement at the beginning of treatment no real arrest of growth took place in any of the cases, so that one cannot speak of the treatment of malignant growths by injection as in any sense a cure. —Brit. Med. Jour.

Honey in Erysipelas.

Dr. C. E. HAYWARD, of Crofton, Ill., writes: "Several years ago, while treating some bad cases of erysipelas, a lady asked me why I did not use the remedy they used in Montana. I asked her what that was; she said honey. I did use it and found it very effective, and since then have used it in every case of erysipelas on any part of the body. My first treatment is the external application of honey. I wash the head and face if necessary, spread the honey thickly on cloth, cut holes for eyes if the face is the part affected, and change the application every three or four hours. I have never had it fail to relieve the pain, heart swelling, and nausea, and to shorten very much the attack. I also give internally the usual remedies for reducing the fever and stimulating the excretories. Three or four days usually suffice to bring about convalescence under this treatment. I have treated numerous cases, but would rather every physician would give it a trial, and I am sure he would find a practical solution to his erysipelas." —N. Y. Med. Jour.

Oil of Capsaicin in Rheumatism.

CARRUT has been known as a great scientific observer and educator for more than five centuries, and it long engaged

repetition as a remedy for apoplexy. In 1861 M. DELVAX recommended Cod liver oil for chronic affections of the respiratory organs, claiming that it led "to diminution of the dyspnoea and cough, and an easier expectoration." During the recent epidemic of typhoid in Dublin, Doctor GEORGE FOX used cod liver oil as a diffusible stimulant in atrophic pneumonia, for which he thinks it particularly suited. It is as quick and powerful a cardiac stimulant as alcohol or ether, and, like these, relaxes the heart by dilating the systemic arterioles; but, unlike ether, it does not diminish sensitiveness of the respiratory centre. He prescribes six-drop doses in molasses, repeated at short intervals; and sometimes adds quinine and tincture of nux vomica.—*Medical Press and Circular*.

Treatment of Diabetes.

ASCOLI reports the case of a man, aged 60, who had suffered from diabetes for two years. The ordinary methods of treatment were tried but without any particular benefit. In the spring of 1895, the symptoms being more acute, inhalations of oxygen were tried. This mode of treatment was practised from March 7th to June 16th, with one week's interval in May. On an average 180 litres of oxygen were inhaled daily. After a few days the urine began slowly to diminish in quantity, lose its high specific gravity, and the sugar sank to 1 per cent. At the end of April the sugar disappeared entirely. In the early part of June no sugar was found even after a meal rich in carbo-hydrates. The body-weight increased 2,500 g. under treatment. The usual dietetic restrictions were observed.—*Brit. Med. Jour.*

An Improved Method of Administering Cod Liver Oil.

WM. F. WAUGH, A.M., M.D., Professor of Clinical Medicine, Postgraduate College of Chicago, in an interesting article on this subject contributed to the *Medical Brief*, in comparing some of the various preparations, says in part: "But a more elegant method of administration is that of Frederick Stearns & Co., of Detroit. The firm prepares wine of Cod liver oil with peptonised iron, which can be taken with readiness by any one who can take wine. There is nothing oily or fishy about the taste, either at the time it is taken or afterwards. During the past winter I have had an opportunity of testing this preparation in many cases, especially at my clinic at the Post-Graduate College. Several forms of pulmonary tuberculosis were treated by it, and with good results. In no case did the wine disagree, even where there was a marked fever. A number of cases presented themselves for debility following influenza, with great mental depression, physical debility, and presenting the clinical picture of neurasthenia. Four of these were treated with this wine, with steady and pronounced improvement. In one case where anaemia had developed, and was progressing in spite of various tonics, the malady was arrested by this wine, and had the hue of health restored to the countenance. In several cases of valvular heart disease, with failure of compensation and evidences of degeneration, the nutrition of the heart seemed to be much improved by the use of the wine.

From the results of a trial in at least twenty cases of the affections named, I would say that in this wine of cod liver oil we have a reconstructive of great value, from which we may obtain all the advantages of cod liver oil, without its very obvious disadvantages. I am pleased to be able to give this commendation to a preparation that is of American origin, and whose composition is plainly stated, so that any physician may prescribe it in such cases as he thinks fit without being compelled to take it on the faith of the import-

er or manufacturer. When the latter simply shows the nature of his products, relying on the purity of the material and skill of its preparation alone for their claims, the physician can utilize the articles, and recommending them intelligently.—*N. Y. Med. Times*.

Pharmaceutical Receipts.

Chlorine Mixture for Throat-affections.

| | | | |
|----------------|-----|-----|------|
| Potass. chlor. | ... | ... | 3i. |
| Acid hydrochl. | ... | ... | mxl. |
| Syrup | ... | ... | 5i. |
| Aque | ... | ... | 5i. |

Drop pot. chlor. into the bottom corner of a dry 8-oz. bottle and pour acid on it. Cork, and when Cl has ceased to be evolved add water and shake well. Add this to syrup in 2-oz. bottle.

Dose: Half a teaspoonful in water every two hours.—*C. & D.*

Antikamnia.

| | | | |
|---------------|-----|-----|---------|
| Acetanilidi | ... | ... | 65 gra. |
| Sodii bicarb. | ... | ... | 30 " |

"PICKED MEN OF A PICKED SERVICE." OFFICIAL BOASTING STILL FURTHER UNVEILED.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—It seems most unfortunate for the discussion that has been raging in the public press on the "Medical Practice Question in India," that some boastful official should have dared to cross swords with his non-official opponents, for the simple reason that the official stronghold is admittedly honeycombed with anomalies, jobberies, inconsistencies and bare-faced scandals of sorts, that could ill afford to have the electric light of public criticism turned upon them. To attempt to bolster up the official cause by any form of argument, meant nothing more than to compel the non-official element to gird up for looks and meet its assailants on their own ground. Unluckily for official medical practitioners, their "free-lance" has entered upon personalities; for while decrying the qualifications

and twisting the idea of their fitness for Hospital and Educational work; he has lauded the *non-official* *sovereigns* up to the skies. "They are all senior men of large Indian experience, they are men who have come to the front rank of their service for special proficiency and attainments in particular lines of their profession or in special branches." "They are men selected by Government and have made their mark in the *motusil*, men who have extracted thousands of cataracts, who have operated hundreds of times for stone, who have constantly performed major operations, who have frequently removed ovarian tumours!"

They are ovariometomists, lithotomists, men who have done scores of ovariometomies, hundreds of operations for stone, cataracts and so forth. Are they the *specialists*, our official apologist and advocate makes them out to be?

Now I maintain that they are not so. Almost every Indian Medical Service man, who is appointed to a chair in the Calcutta Medical College, is and was (going back to the earlier and even modern history of the College) NO SPECIALIST, whatever time, opportunity and practice may have made of him subsequently. Let us begin with Surgery. SIR JOSEPH FAYRER may be dismissed with a mere reference to his work called "*Clinical Surgery in India*." A more fatalistic record of surgery can hardly be found. He *did* surgery as this book shews, but we stand appalled at the results. Succeeding FAYRER came BOWEN PARTRIDGE, a born surgeon and a most successful and brilliant operator. His equal has not been found since he retired. But with all his latent and inherent surgical skill, PARTRIDGE came to the Medical College *not* as a specialist in *surgery*, but to fill the chairs of botany and chemistry! He *was* not a specialist in surgery, he certainly *became* one afterwards. PARTRIDGE was succeeded by KENNETH MCLEOD, another excellent surgeon, a man who did credit to the choice of Government, but the records of the College prove that MCLEOD came to his work *not* as a specialist, but as a novice. His office for years as Secretary to the Surgeon-General was not calculated to inculcate either a love for anatomy or zeal and efficiency in surgery. MCLEOD is alive and well, and will not deny that *lithotomy* was *not* a successful operation under his knife. MCLEOD was followed by RAYE, and the latter by O'BRIEN, but without going into details of the work of men still among us, I will only say that I may safely challenge DR. JOUBERT to prove by any record of statistics, official or private, that either of these able and learned gentlemen approached the chair of surgery with the mantle of a SYME or a LISTER, or with the reputation for surgical skill of a TREVES or a WALSHAM, or a JOSEPH BELL.

Now to obstetrics and gynaecology. In my last letter of the 1st November, I shewed beyond doubt, that recent appointments to this chair, in no way supported DR. JOUBERT's boast that their incumbents came to their office imbued with "special proficiency and attainments in this special branch." Going backwards in this chair, surely our official apologist knows that DR. HARVEY came to his work in this line as a novice and had to be trained by DR. T. EDMUNSTON CHARLES, his predecessor. A man who has filled the chair of obstetrics or gynaecology in Calcutta, has come to it with the reputation of being

an ovariometomist, though the boast is that "they were men who had a record of doing scores of ovariometomies." The fact is exactly the reverse. Our "professors" in this "line" were *not* ovariometomists, if the fatal records of the statistics of this operation are to be relied on during the incumbency of Professors CHARLES and HARVEY. Let the record be published and my assertion will be amply vindicated. So much for this vain boast. But why go further! A mere *Gazette* republication of the various incumbents will prove that with one or two rare and recent exceptions the officials who have been pitch-forked into these Hospital and Educational appointments at the time of their "gazetting," could hardly in a single instance, come honestly within the scope of being styled "picked men of a picked service and in the front rank for special proficiency in special branches." It is true they are often "picked men," but "picked" not for merit and skill, but for reasons which "social officialism" might more competently and conveniently explain.

I trust we shall hear no more of these ugly comparisons, for comparisons are always odious, yet under provocation and in self-defence, I have been compelled to drag in personalities, and perhaps for the controversy as it concerns independent physicians, it is just as well the opportunity was forced upon us by an official.

Yours, &c., W. C.

THE CAUSE OF THE LOCAL PROFESSION. TO JAMES R. WALLACE Esq., M.D., L.R.C.P. & S., L.S.A. Secretary, Indian Medical Association.

SIR AND CONFRERE,—*Apropos* of the distressing state of affairs as at present obtains with the Anglo-Indian and Indian community in India and of civil medical practitioners in particular, a correspondent suggests the desirability of sending a delegate to Europe to plead our cause. He is *right*, Sir, very right, as since DR. ERNEST HART's strictures on the I. M. S. a decided effort is being made by those who have "to receive more and to take away from those who have not the *little* that they have struggled hard to obtain," and inch by inch our prestige is being slowly but so surely wrested from us, that unless we make a determined stand for life and liberty, we shall soon be a mere cipher in the land we helped to build and keep for England's gain and glory.

Two main difficulties are presented :—(1) The expenses of the undertaking with its to and from journey and the money needed for the keep of the delegate for the four to six months that he will necessarily have to stay to gain the ear of the powers that be, and (2) who should or ought to go.

Those of us whom Providence has dealt kindly with are (no matter how willing they may be to do so) unable to plead, because having never worn the tight shoe they cannot feel how it pinches or tell where it really hurts. Those who have large practices or business firms have too many private interests to protect, to enable them to give this important subject and our actual grievances the undivided and unhampered attention they require. Some have never given the matter a second thought, because it did not just then directly affect them, and they dreaded to peer into the veil of the future, while others are not in a

position as fully explained. These men, however, are not content with the literary character of the situation or picture that their statements present, if malitiously not, sound and true, yet empty. All the few who thoroughly grasp the whole matter in all its bearings, both present and future, the majority unfortunately are unable to exert a representative speaking, because they have never mixed in public life, have no journalistic connections, and never having addressed a public assemblage through the press or in the future, they are consequently too retiring to write or speak in public, both of which require considerable nerve and practice.

Some one proposes a "Royal Commission of Enquiry," but as the late Opium, Leprosy, and Vaccination Commissions afford the firm conviction that no good will accrue to us, as everything, no matter how solemnly true, that militates against traditional conservatism will run the risk of rigid exclusion, and I scarce think it wise to trust ourselves and the future of our children to the "thousand against" to "one for us" chance of such a Commission, when our only remedy lies in agitation and straightforward, honest representation of matters as they really stand.

The position is a truly serious one, and with all due modesty, I beg to submit that springing as I do from a long list of journalists and public speakers (five generations in direct line) with a large press connection and having for years carefully studied these matters in every one of their aspects, I would be well fitted for this important mission, as besides being a medical man who has held Military, Civil and Municipal office, which have daily brought me in contact with all manners and conditions of men, I am a journalist and public speaker of several years' standing with a fairly large connection with the more important portion of the British lay and medical press.

Living as I have always done, and striving my level best for the public good, I have eschewed a "family practice" and any and every business that tying me down to any one place would force me to protect private interests and neglect the aims and ambitions of the Anglo-Indian community of which I am proud of being a blood-member.

Therefore, Sir, as there is absolutely nothing to detain me, and as I have nothing to distract my attention from agitating the British press and public for the alleviation and bettering of our condition I am free to start, as soon as the Indian Medical Association thinks fit to send me as its delegate, and am quite prepared to stay in England for as long a period as it requires me to, provided that I am furnished with the most moderate expenses for myself and family for such time as the I. M. A. wishes me to fight our cause.

More easy terms than these you cannot obtain, and while in your capacity as Secretary to our Association, I ask you to send this letter before the "Council" for consideration. I, in the public interest, claim the favor of your inserting my proposal in the Indian Medical Record, so that those of your subscribers who have not yet joined the Indian Medical Association may be so advised as early that we may

have in it a paper of considerable interest and value.

Yours, &c., **WILLIAM D. BARNES, M.D., F.R.C.S.**

Calcutta, 24 November 1901.

We believe Dr. Barnes to be not alone among the medical men of India who can express an opinion on the matter calmly and fairly. He has been elected to the Council of the Indian Medical Association. His impartiality and objectivity is evidenced by the fact that he has been elected to the Council of the Indian Medical Association who may be deemed to be impartial to large—B.D., I.M.A.

CIVIL APOTHECARY.

TO THE EDITOR, INDIAN MEDICAL RECORD.

SIR,—I trust you will extend your support to this branch of the Subordinate Medical Service as generously as you have done in the case of the Military and Civil Assistant Surgeons and Hospital Assistants.

The Civil Apothecary class was opened about 20 years ago to take the place of the Military Apothecaries at civil stations when the services of the latter were required for purely military purpose and they have invariably given good account of themselves in the various and responsible duties required of them. Now that the Military Apothecary has been given the decent and very appropriate designation of Assistant Surgeon, I think it would only be fair that the Civil man gets it also. But the mere title is not enough; it should be accompanied by an increase to his miserably poor salary. Why should not he be paid like the military brother, when he is on an equal footing with him in professional education, and is found to fill his place in civil life with entire satisfaction? Many of the Civil Apothecaries (nearly one-third of their present number) are holders of University degrees (L.M.S., &c.), and since the year 1888, the Service is recruited not as it was and as the military branch still is, by men educated at Government expense, but from private students who have taken the L.M.S. degree. But I believe it has been found difficult to get these men, as the present pay and position are not sufficiently attractive. The pay is a mere pittance, starting with Rs. 50 and rising after a life-time of service to Rs. 150 plus an allowance of Rs. 50 for an independent charge. This is barely sufficient for any honest man to live decently on, much more to enable him to purchase books and journals, so that he may keep himself abreast with the advancing times in professional knowledge.

The present Surgeon-General with the Government of Madras knows the Civil Apothecaries well, and is fully aware of their worth, as he was for a long time a professor of the Madras Medical College; and I have no doubt that he will make just proposals on their behalf when a proper opportunity occurs; and may that be in the near future.

Yours, &c., **CIVIL APOTHECARY, &c.**

SUSPICIOUS REMITTENT FEVER.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I have recently in my patients come across cases of "fever" which, in the first instance, is of a remittent type, but which, after a few days, changes to an intermittent type. I have described in the Record of the 1st March 1902, the

The patient of Bombay. I looked upon this case with interest, being that it was on the border land of, if not within the sphere, of typhoid, notwithstanding that I have heard of the doubts which exist as to the possibility of natives being affected with this much-debated disease. All the characteristic symptoms were to be observed here in more or less modified form, such as the persistent and high temperature in spite of every endeavor at reduction, including the wet pack, the frontal headache, the white furred tongue gradually and surely reddening at both tip and edges, only shortly after to pass again into the dry brown condition; the light yellow semi-solid stools, tympanitis and gurgling in right iliac fossa. Spots were looked for but not seen. Pains simulating hepatitis were present in liver, which with the fever was one of the early symptoms observed. This tenderness, however, did not last more than four days when, under the usual treatment, it subsided entirely. On about the 9th day of the fever he got acute pains in both knees, all the other joints remaining unaffected. The high temperature kept on, until the 16th day when he was, strictly against advice, removed from medical treatment by his father, with the object of being taken to his country. He died the same evening. In the words of Dr. RAM KISHEN where he says as regards typhoid in natives that "it affects the brain and liver, diarrhoea is often present, tongue is dark, dry and rough, and the eyes are sunken, and that, do whatever we may, the fever never leaves before its time is up." He conveys to us exactly the conditions I observed in the case above put forward. My two other cases of suspicious fever in natives occurred in people who were in the close vicinity of the first one, and soon after which they made their appearance. We had here the same persistent temperature in face of judicious endeavours at bringing about a reduction, and almost the same condition of the tongue and a sluggish liver, with a tendency to constipation. In the one the temperature fell to normal on the 8th morning, and in the other on the 7th. All three of these cases I recognised as remittent fever, the first, severe, and the two last, mild.

Yours, &c., A. BEALE,
In medical charge R. I. M. S. "Clive."

BOMBAY SUBORDINATE MEDICAL DEPARTMENT

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I am glad to see that your correspondent "Sympathy" has realised the poor prospects of the 1894 batch of 3rd class Assistant-Surgeons. How long will the 1895 batch and those coming out of College hereafter have to wait for promotion? The officers of the A. M. S. and I. M. S. get promoted by length of service, also the Military Assistant Surgeons and the Civil Assistant Surgeons and Hospital Assistants in Madras and but with Military Assistant Surgeons of the Bombay service it is a case of jumping into dead man's shoes. Is this sad state of affairs to last for ever? Some years ago, a similar batch in promotion occurred in Madras, but when the matter was represented, the present ruling was brought into force, viz., promotion by length of service. I would ask why this privilege was not extended to the Military Assistant Surgeons of the Bombay service, who are in

every respect as well qualified as their counterparts in Madras. Surely what's good for the goose is good for the gander. When the unfortunate batch of 1891 came out of the Grant Medical College, there were about 100 3rd class Assistant Surgeons in place of 100, which is the number allowed, and to add to their misfortune a number of supernumeraries in the other grades had to be absorbed, hence the present block in promotion. At the present time there are eighteen, and the batch coming College will furnish at the very least eight, bringing up the total to twenty-six, which is more than twice the number allowed, with an increase every succeeding year. Can any one now wonder at the slow promotion? This is a long-standing grievance, and one that requires thorough investigation. The sooner this is done the better. It will remove the present discontent, and the work will be carried out more cheerfully.

Yours, &c., DISAPPOINTED.

MILK SUPPLY OF THE ARMY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In the 1st September issue of your paper, page 195, your correspondent, Mr. M. VERGHSE, under the head of "The Milk Supply of British Troops in India" was very eloquent over the woes of Tommy Atkins and the milk question. May I be allowed to inform him that Tommy Atkins is very much better looked after in this respect, at all events in hospital, than Mr. VERGHSE supposes, seeing that for some years we have supplied the Indian Government, expressly for use in the hospital, with large quantities of the "First Swiss" Brand of unsweetened condensed milk. Your correspondent must not scoff when he reads the words condensed milk, for the unsweetened milk is a very different thing from the well-known ordinary sweetened condensed milk. First it contains no sugar (added), then the presence in it of the murderous bacteria is an impossibility, because any disease germs that may by chance have found their way into the milk would be absolutely destroyed by the great heat used in the process of manufacture, then boiled water is used when mixing. Tommy has the purest, richest and best milk this world supplies, indeed far purer than if taken direct from the cow, the flavor also, unlike that of ordinary sweet condensed milk is unimpaired, nay it is enriched. Now these things being so, let Mr. VERGHSE be happy in the knowledge that "Lord Bull" is not after all so careless as to the well being and comfort of Tommy as many suppose.

Yours, &c., A. J. MARTIN.

PIGMENTATION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will any of your readers kindly inform me of any preparation for effacing or at least lightening the copper-colored pigmentations of secondaries, as I have a number of such cases in hospital at present, and they persist after continued applications of unguentum hydrargyri emulsionem?

Yours, &c., THOMAS VICTOR.

Have you tried the double chloride of gold and sodium in 41 grain doses morning and evening?—S. J. M. D.

LIQUOR EPISPASTICUS IN WARTS OF THE GENITALS.

To the Editor, "INDIAN MEDICAL RECORD."

Sir.—Perhaps it is not generally known that Liquor Epispasticus lightly painted over genital warts, say morning and evening, until they drop off, is a rapid and most effective method of getting rid of this filthy affection. The excoriation of superficial mucous membrane, which is liable to occur to some slight extent, however carefully this preparation be applied, can be healed up in a couple of days with simple dressing. Dealing with these cases in this manner does away with the painful process of snipping the fungus off with the scissors, often a not very easy task, as when we have the cauliflower excrescences to deal with, made up of all base and very short proliferations, the operation is, as a rule, accompanied by severe bleeding, after the suppression of which remedies such as nitrate of silver or nitric acid are applied with, in very many instances, a recurrence of the disease, not only on the old sites, but also on adjacent parts. This cantharidine line of treatment I first saw practised by Surgeon-Major C. A. WRESE, A. M. S., and the complete success with which I always found this procedure followed was remarkable. It has many advantages over the commoner remedies. It does away with the sense of fear of pain about to be inflicted when the scissors, nitrate of silver, &c., are proposed to the patient, there is no obstruction from this cause to its free application and the perfect eradication of the disorder; the pain if any, resulting from excoriation, is so transient that the subject never speaks of it; and the cure is permanent, with no fear of adjacent infection.

Of course great care must be taken in applying this remedy and to limit, as far as possible, its action to the warts themselves. A layer of dry lint over the solution after it has been coated on will protect surrounding parts.

Yours &c., A. B.

Government Medical Gazettes.*

GOVERNMENT OF INDIA.

Surgn.-Col. T. Maunsell, A.M.S., to offg. as P. M. O. Bengal Command from 15th Oct. 1895, *vice* Surgn. Maj.-Genl. T. Walsh on leave.

Surgn.-Capt. T. E. Swinton, I.M.S., to be personal Asst. to P. M. O. Bombay Command, from 1st Oct. 1895.

Surgn.-Capt. H. R. Woolbert, M.B., I. M. S., to revert to med. charge Deolali Irregular Force and Harrowtee and Tonk agencies on 1st Oct. 1895.

Third grade Hosp. Asst. Gagan Singh is permanently attached to the Burmah Civil. Dept. from 19th Sept 1895.

BENGAL GOVERNMENT.

Leave is sanctioned as under:—Surgn. Lieut.-Col. J. O'Brien, 5 days extension.

Surgn.-Capt. N. P. Sinha, for 10 months and 28 days from 18th Nov. 1895.

Dr. C. Banks for 5 weeks, from available date; Dr. J. L. Hendley, 11 days, from 21st March 1895 as permitted extension.

Asst. Surgn. N. P. Bann, 2 months extension; N. O. Banerjee, 6 months extension; A. L. Moosumdar, 8 months from available date.

The following officers are placed at the disposal of the Insp.-Genl. of Jails:—Surgn.-Capt. B. C. Oldham, and F. P. Maynard.

* Continued on 16th November.

The following appointments are made:—

Surgn.-Capt. E. Bird to be Civil Surgeon of Hyderabad.

Dr. N. O. Meekari to be civil med. Asst. at Secunderabad. Surgn. F. Mitter to med. charge Secunderabad Disp.

Medical charge was made over as under:—Asst. Surgn. K. N. Banerjee, of Dinapur Jail, on 26th Oct. 1895; and N. G. Mitter, of Arrah Jail, on 26th Oct. 1895.

Medical charge was assumed as under:—Surgn.-Lieut. Col. W. F. Murray, of Arrah Jail, on 26th Oct. 1895.

Surgn. Lieut. R. M. Blaker, of Dinapur Jail, on 26th Oct. 1895.

The following Civil Hosp. Assts. to have the higher grade pay from 21st Oct. 1895:—

Second Class.—Nishi Kanta Dass and Baroda Prosad.

Third class.—Syed Mahomed Abbas Shakur; Satish Chandra Acharye; Baidya Nath Giri; Lakshmi Narayan Mitter; Saroda Prosad Sen; Bhagawat Parshad.

PUNJAB GOVERNMENT.

The following acting appointments among Civil Surgns. are notified:—

Second Class.—Surgn. Maj. C. J. Bamber, from 26th Sept. 1895. Surgn.-Capt. D. T. Lane, from 5th Aug. 1895.

Power to conduct *post-mortems* in Dera Ghazi Khan Dist. is granted to the Hosp. Asst. attached for the time being to the Rojhan Disp.

Leave of absence is sanctioned as under:—First class Hosp. Asst. Daulat Ram, 15 days *p.l.* from 4th Sept. 1895.

Second class Hosp. Asst. Sobha Ram, 6 months on *p.a.* from 17th Oct. 1895.

Third class Hosp. Asst. Abdul Hamid Khan, 3 months from 26th Oct. 1895; Hira Singh, 15 days from 8th Oct. 1895; Ibrahim, 6 months' furlough from 12th November 1894.

The following assumed charge:—Bde.-Surgn. Lieut.-Col. W. A. C. Roe, of Insp.-Genl. Civil Hosp. Punjab, from 24th Oct. 1895. Surgns.-Maj.—J. W. Rodgers of civil med. duties, Dera Ghazi Khan Dist., from 9th Oct. 1895; M. O'Dwyer of civil med. duties, Jullunder Dist., on 16th Oct. 1895; Surgn.-Capt. H. Fooks of civil med. duties, Bannu Dist., on 16th Oct. 1895; Mily. Asst. Surgn. J. T. Weston, of Supdt. Hissar Jail, on 10th Oct. 1895; Asst. Surgn.—Khan Bahadur Chetan Shah of civil med. duties, Ludhiana Dist., on 18th Oct. 1895; Bhagat Ram of Sany Offr., Kalka, on 1st Oct. 1895; More Chand of Mooltan Dist. Jail on 27th Sept. 1895; Diwan Ali of Pindighat Disp. on 23rd Oct. 1895.

The following made over charge:—Bde.-Surgn. Lieut.-Col. B. Franklin of Insp.-Genl. Civil Hosps. Punjab on 4th Oct. 1895.

Surgns.-Maj.—M. O'Dwyer of Dy. Sany. Comr., Punjab, on 16th Oct. 1895; S. F. Bigger of Civil med. duties Banna Dist., on 16th Oct. 1895.

Surgn.-Capt.—D. M. Davison of civil med. duties, Gurdaspur Dist., on 18th Oct. 1895; H. Headley of Supdt. Dharamsala Jail on 25th Sept. 1895; E. N. Morris of Supdt. Mooltan Dist. Jail on 27th Sept. 1895.

Surgn.-Lieut.—E. A. R. Newman of civil med. duties Dehra Ghazi Khan Dist., on 9th Oct. 1895.

Asst. Surgn.—Brijal of civil med. duties Ludhiana Dist. on 19th Oct. 1895; Sobha Ram of civil med. duties, Jullunder Dist., on 16th Oct. 1895; Radha Kishan Rai Bahadur of civil med. duties, Gurdaspur Dist., on 18th Oct. 1895; Harbhagwan Das of Sany. Office, Kalka, on 1st Oct. 1895; Gobind Ram of Chisnot Disp. Jhang Dist., on 11th Oct. 1895; Fateh Chand of Supdt. Hissar Jail on 10th Oct. 1895; Gobind Ram of Mooltan Normal School on 12th August 1895; J. D. Bebelro of civil med. duties Sheikh Batin on 26th Oct. 1895.

BOMBAY GOVERNMENT.

From the 6th Nov. 1895, Surgn. Capt. J. Jackson, M.B., Supdt. Hyderabad Central Prison, is vested with the powers of a 3rd class Magistrate.

Surgn. Lieut.-Col. M. L. Bartholomew is nominated as a member of the Ambahabad Municipal Board.

The Deccan Gang was placed under the medical charge of Asst. Surgn. A. G. Baker on 18th Oct. 1895.

FORUM.—On the 23rd October, at Suva, C. P., the wife of Suva, Capt. F. J. W. Porter, M. B. N., of a daughter.

It is characteristic of conspiracy that it tends to spontaneous disruption. Whether we deal with great or small combinations of this kind, with the quasi-sublime or with the ridiculous in imposture, the result is the same. A quarrel or a bribe may at any time introduce the thin end of the wedge, and the further work of cleavage is only a question of time. It is usually to the public advantage when offenders, thus break with each other, and a degree of satisfaction on the part of outsiders is at such times only natural. Sometimes, however, this feeling is tempered by a touch of pity, as in a case recently examined in the Southport police-court. A youth eighteen years of age was charged with sleeping out of doors. He defended himself on the plea that his master, a professional hypnotist, had refused to pay him his wages. Some remarkable statements which follow throw a light on the kind of relations which exist between the hypnotist magician and his medium. According to his own admissions the sufferings of this unfortunate "subject" were not imaginary. The art of the master juggler did not extend to the abolition of sensation. A pretended trance in which he lay for three days with his mouth stitched up was to the boy a period of wakeful and doubtless of painful sensibility, and we may safely conclude that certain injuries inflicted upon him at other times were likewise unrelieved by the anaesthesia of suggestion. The folly of enduring—the morbid and culpable folly of encouraging—these miserable impostures ought to require no demonstration. Their exposure in this instance will, if it is to be hoped, have some influence in weaning the minds of a credulous public from the attraction of a species of fraud to which it is far too ready to expose itself. We will not deny the strict justice of leaving the knave and his willing dupes in cases of this kind to live on one another and to find each other out. Still, this admission does not absolve us, as humane beings, of a certain social responsibility in the matter. Where the effect of the imposture implies no great personal detriment it may be allowed to work its own cure. Where, on the other hand, persons like the youth above mentioned are comparatively incapable of self-defence and are liable to somewhat serious injury, it will be generally admitted that some form of official supervision, and even at times of interference, is called for.—*Leader*.

GENERAL ARTICLES

THE FUTURE—PAST AND PROSPECTIVE— OF MEDICAL AND SANITARY WORK IN INDIA.

Mr. Bagg, Surge. Lieut.-Col. Kenneth MacLeod.

M.A., M.D., LL.D., F.R.C.S., Edin.

Questions of medical reorganisation and sanitary development in India are at the present time undergoing keen discussion. There seems to be a general consent that some change is necessary and impending; but the grounds on which that change is needful and the manner in which reform is to be accomplished do not appear to be always clearly defined. Service considerations loom too large in the argument, and it is not sufficiently held in view that medical and sanitary administration must constitute a part of general administration; and that questions of reorganisation must turn upon the condition and requirements of the country, and not upon the history or qualities or rights of present establishments, or the claims and qualifications of those who clamour to replace them. A review of the evolution of general and medical administration in the past is necessary in order to understand clearly the faults of the present and needs of the future in respect of medical and sanitary work.

For this purpose I have drawn up a table in which the more prominent features of the history and administration of India, since the granting of a charter to the East India Company in the year 1600 up to the present time, are stated on one side, and the consequent changes which have taken place in the strength and constitution of the medical services are shown on the other.

Scheme of Administrative and Medical Evolution in India.

Historical.

Seventeenth Century. Factories; writers, native agents and subordinates; ships; a few soldiers.

Eighteenth Century. Acquisition of territory by coasts and conquests; wars; armies, white and black; navy. Civil administration, by presidencies and districts, of acquired country; collectorate course of justice, police. Police established, and subordinate, revenue, judicial and clerical services organized.

First Half of Nineteenth Century. Extension of territory; increase of army and navy; subordination of new provinces; control of civil governments multiplied; provincial administrations created; considerable attention paid to education and medical relief; peace, protection, and commerce extending.

1857. The Indian Mutiny. Motives, organization; of military establishments and civil government; suppression of mutiny; organization of Maratha army; reorganized police administration.

1858-60. The British East India Company dissolved, and government of India passed to the Queen.

From Administrative position in Government. Transfer of Government from the Company to the Queen.

Administrative, military and civil. Main features in general history of the Government of India from 1858 to 1900; last thirty years of the Government of India.

1858-63. Indian Medical Service created; civil medical service largely entrusted to trained Indians and "Europeans." Increase of subordinate and subordinated medical services.

1860. Indian Medical Service reformed. Officers restricted to charge of native army and civil employ.

1861. Administration of British Army hospitals and medical staff entrusted to British Medical Officers.

Introduction

Manifestation of great sickness and mortality among soldiers, prisoners and population. Depreciable sanitary condition of country becomes evident.

1873. Lord Mayo's policy of decentralization gives increased responsibility and power to local Governments. Considerable increase of activity in medical and sanitary matters follows.

Efficiency of separating military and civil medical administration fully realized. Programs in public medical relief, medical education, sanitation, vaccination, and vital statistics continues.

1882. Lord Ripon's scheme of local self-government elaborated. Municipalities and local bodies created and entrusted by law with power of collecting and spending money for local purposes—medical relief and sanitation among them.

1998, 1999, 2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010, 2011, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019, 2020, 2021, 2022, 2023, 2024, 2025, 2026, 2027, 2028, 2029, 2030, 2031, 2032, 2033, 2034, 2035, 2036, 2037, 2038, 2039, 2040, 2041, 2042, 2043, 2044, 2045, 2046, 2047, 2048, 2049, 2050, 2051, 2052, 2053, 2054, 2055, 2056, 2057, 2058, 2059, 2060, 2061, 2062, 2063, 2064, 2065, 2066, 2067, 2068, 2069, 2070, 2071, 2072, 2073, 2074, 2075, 2076, 2077, 2078, 2079, 2080, 2081, 2082, 2083, 2084, 2085, 2086, 2087, 2088, 2089, 2090, 2091, 2092, 2093, 2094, 2095, 2096, 2097, 2098, 2099, 2100, 2101, 2102, 2103, 2104, 2105, 2106, 2107, 2108, 2109, 2110, 2111, 2112, 2113, 2114, 2115, 2116, 2117, 2118, 2119, 2120, 2121, 2122, 2123, 2124, 2125, 2126, 2127, 2128, 2129, 2130, 2131, 2132, 2133, 2134, 2135, 2136, 2137, 2138, 2139, 2140, 2141, 2142, 2143, 2144, 2145, 2146, 2147, 2148, 2149, 2150, 2151, 2152, 2153, 2154, 2155, 2156, 2157, 2158, 2159, 2160, 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2172, 2173, 2174, 2175, 2176, 2177, 2178, 2179, 2180, 2181, 2182, 2183, 2184, 2185, 2186, 2187, 2188, 2189, 2190, 2191, 2192, 2193, 2194, 2195, 2196, 2197, 2198, 2199, 2200, 2201, 2202, 2203, 2204, 2205, 2206, 2207, 2208, 2209, 2210, 2211, 2212, 2213, 2214, 2215, 2216, 2217, 2218, 2219, 2220, 2221, 2222, 2223, 2224, 2225, 2226, 2227, 2228, 2229, 2230, 2231, 2232, 2233, 2234, 2235, 2236, 2237, 2238, 2239, 2240, 2241, 2242, 2243, 2244, 2245, 2246, 2247, 2248, 2249, 2250, 2251, 2252, 2253, 2254, 2255, 2256, 2257, 2258, 2259, 2260, 2261, 2262, 2263, 2264, 2265, 2266, 2267, 2268, 2269, 2270, 2271, 2272, 2273, 2274, 2275, 2276, 2277, 2278, 2279, 2280, 2281, 2282, 2283, 2284, 2285, 2286, 2287, 2288, 2289, 2290, 2291, 2292, 2293, 2294, 2295, 2296, 2297, 2298, 2299, 2300, 2301, 2302, 2303, 2304, 2305, 2306, 2307, 2308, 2309, 2310, 2311, 2312, 2313, 2314, 2315, 2316, 2317, 2318, 2319, 2320, 2321, 2322, 2323, 2324, 2325, 2326, 2327, 2328, 2329, 2330, 2331, 2332, 2333, 2334, 2335, 2336, 2337, 2338, 2339, 2340, 2341, 2342, 2343, 2344, 2345, 2346, 2347, 2348, 2349, 2350, 2351, 2352, 2353, 2354, 2355, 2356, 2357, 2358, 2359, 2360, 2361, 2362, 2363, 2364, 2365, 2366, 2367, 2368, 2369, 2370, 2371, 2372, 2373, 2374, 2375, 2376, 2377, 2378, 2379, 2380, 2381, 2382, 2383, 2384, 2385, 2386, 2387, 2388, 2389, 2390, 2391, 2392, 2393, 2394, 2395, 2396, 2397, 2398, 2399, 2400, 2401, 2402, 2403, 2404, 2405, 2406, 2407, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417, 2418, 2419, 2420, 2421, 2422, 2423, 2424, 2425, 2426, 2427, 2428, 2429, 2430, 2431, 2432, 2433, 2434, 2435, 2436, 2437, 2438, 2439, 2440, 2441, 2442, 2443, 2444, 2445, 2446, 2447, 2448, 2449, 2450, 2451, 2452, 2453, 2454, 2455, 2456, 2457, 2458, 2459, 2460, 2461, 2462, 2463, 2464, 2465, 2466, 2467, 2468, 2469, 2470, 2471, 2472, 2473, 2474, 2475, 2476, 2477, 2478, 2479, 2480, 2481, 2482, 2483, 2484, 2485, 2486, 2487, 2488, 2489, 2490, 2491, 2492, 2493, 2494, 2495, 2496, 2497, 2498, 2499, 2500, 2501, 2502, 2503, 2504, 2505, 2506, 2507, 2508, 2509, 2510, 2511, 2512, 2513, 2514, 2515, 2516, 2517, 2518, 2519, 2520, 2521, 2522, 2523, 2524, 2525, 2526, 2527, 2528, 2529, 2530, 2531, 2532, 2533, 2534, 2535, 2536, 2537, 2538, 2539, 2540, 2541, 2542, 2543, 2544, 2545, 2546, 2547, 2548, 2549, 2550, 2551, 2552, 2553, 2554, 2555, 2556, 2557, 2558, 2559, 2560, 2561, 2562, 2563, 2564, 2565, 2566, 2567, 2568, 2569, 2570, 2571, 2572, 2573, 2574, 2575, 2576, 2577, 2578, 2579, 2580, 2581, 2582, 2583, 2584, 2585, 2586, 2587, 2588, 2589, 2590, 2591, 2592, 2593, 2594, 2595, 2596, 2597, 2598, 2599, 2600, 2601, 2602, 2603, 2604, 2605, 2606, 2607, 2608, 2609, 2610, 2611, 2612, 2613, 2614, 2615, 2616, 2617, 2618, 2619, 2620, 2621, 2622, 2623, 2624, 2625, 2626, 2627, 2628, 2629, 2630, 2631, 2632, 2633, 2634, 2635, 2636, 2637, 2638, 2639, 2640, 2641, 2642, 2643, 2644, 2645, 2646, 2647, 2648, 2649, 2650, 2651, 2652, 2653, 2654, 2655, 2656, 2657, 2658, 2659, 2660, 2661, 2662, 2663, 2664, 2665, 2666, 2667, 2668, 2669, 2670, 2671, 2672, 2673, 2674, 2675, 2676, 2677, 2678, 2679, 26

1967, CIVIL RIGHTS, and
 organized. For example, the
 against their own interests.

1966 Kentucky Constitution
with the Government of the
United States.

The "Frodoth" Society has
announced that. Overcoming
friction between medical and nursing
departments and between hospital
and municipal medical departments.

Previous arrangements into medical and military matters were left there were made, and some interposition of military medical departments.

1905. Military medical administration unified, separated from civil and placed under one head. Civil and military institutions re-organized and placed under control of provincial governments. Licenses and graduates of Indian medical schools ending in practice in territories and states.

Local bodies suggest and found hospitals and dispensaries, and employ medical subordinates for medical and sanitary purposes. Great increase of sanitary work, and closer attention to health matters in general.

From this bird's-eye view of Indian administration, it is evident that our Government of the Empire has been pervaded by several well-defined principles, chiefly (1) Military unification; (2) separation of civil from military administration; (3) decentralisation of civil government; and (4) development of local self-government. It is on these lines that progress will proceed in the future, and any change which is considered necessary in the interests of the country ought to take the shape of gradual development rather than abrupt revolution.

The recent creation of four army corps under one chief is another step towards consolidation of the military forces of India. Probably a higher degree of assimilation of the native to the European section of the army will result in the course of time; and the question of amalgamating and unifying the Army Medical Executive, medical administration having already been amalgamated and unified, will eventually arise. Meantime the differences of constitution and location of the two sections of the Army, and the different conditions under which the medical executive of each are engaged, will probably militate against consolidation of the latter.

Military and civil medical administration have been completely separated since the year 1880 and the system then commenced has worked well. No complaint has arisen from the Governments under which they have acted of inefficiency or neglect on the part of that section of the Indian Medical Service which is employed under civil administrations. On the contrary, it is allowed that the work has hitherto been done well, and that officers of the Indian Medical Department have rendered splendid services in war and peace—in medical relief, sanitation, vaccination, education, the management of prisons and asylums, and in many other capacities. It is true that they are primarily recruited for military service, are trained in the Army Medical School at Netley, have to serve two years with the colours and are liable to recall from civil employ in case of military exigency. As a matter of fact, this recall has seldom taken place since the 1880's, and as a matter of experience, these officers are doing the work—rather the better as regards status and remuneration—for their military

training. It was once the fashion to disparage military medical work—it consists after all in treating the sick and wounded and improving the sanitation of barracks, lines, cantonments, and camps. In India it is frequently confused with civil work. The work is by no means petty nor the men incompetent, and the reduction of the death-rate of the European army from 69 to 12 per 1,000 is no mean achievement.

Equally anachronistic is the phrase "fossil seniors." Administrative officers in these days are the survival of the fittest, and are carefully selected both at home and abroad. That the liability to recall to military duty has not damaged the work of civil surgeons in India is quite certain. Whether the policy of maintaining in this manner a reserve of medical officers for military contingencies is expedient and sound or otherwise must depend on administrative considerations; especially on the question, how far the contingency of military exigency on a large scale can be banished from Indian thought. The recent cry for a purely civil service has arisen from an interested class which hopes to profit by the change, and not from those who rule the country and administer its military and civil affairs.

Even if it were decided to be advisable on administrative grounds, to entertain a purely civil medical service, it would be necessary to obtain the same class of men as at present and in a similar way. The primary duty of civil medical officers is to attend on Government officials and their families, and take charge of Government institutions, Europeans, or Europeanised persons, are obviously best fitted for these purposes, and the universal rule in India that all official departments must, for efficiency and progress, be officered in chief by Europeans cannot with impunity be set aside in the case of the medical and sanitary services. Plenty of employment has arisen, and more will arise, as the country develops, for Indians, educated in India, without destroying arrangements which have hitherto worked so well.

The real cause of dissatisfaction with medical and sanitary services in India, as now constituted is that disease and death are yearly ravaging the country; that sanitation is in a very backward state, and that these services are feeble in the face of conditions, making for deterioration of health and destruction of life throughout a vast area covered by an immense population. What are a few hundred doctors and a few score sanitarians to the 280 millions of India? All this is quite true; but does the remedy lie in multiplying and debasing the medical and sanitary executive, and is it the duty of Government to carry medical relief to every door and compass the cleansing of every home?

The remedy consists rather in following out the lines of policy—decentralisation, and self-government—already initiated, and developing the spirit and practice of self-help and self-support among the people. This has been already done largely as regards medical relief, but it is even more necessary in matters of sanitation. Medical relief requires a skilled agency, but the work of cleansing, which ought to commence with the home, can and must be wrought by the people themselves.

It is absurd to contemplate an army of sanitarians and

scavengers sweeping the Indian Empire. The head of the home must be held responsible for the cleanliness of the household, the urban authority of the town, and the district and provincial authorities for the execution of important works necessary for the health of the community at large. The duty of Government consists in showing why and how sanitary measures are to be undertaken. By means of advisers and inspectors the sanitary needs of the country and community are ascertained, and this done, the ruling power sought to insist on the proper steps being taken by the local authority to secure cleanliness and prevent practices dangerous to health. The present advising and inspecting agency requires strengthening and organising, and arrangements have to be made for the scientific study of disease causes.

But sanitary progress must depend on sanitation becoming part and parcel of the rule of the country and life of the people as in England. As development proceeds in this direction there will be abundance of employment for Indian medical men.

I have in these remarks designedly limited myself to principles, and avoided comment on particular proposals and plans of medical re-organisation.

The points which I have endeavoured to establish may be summarised in these three propositions:—

1. The sanitary defects and defaults of India do not result from any ignorance or incapacity on the part of the Indian Medical Service, but depend upon the circumstances and habits of a teeming and ignorant population spread over a vast extent of unhealthy country.
2. The arrangements for medical aid to Government servants and medical charge of Government institutions and for medical administration are satisfactory; but the arrangements for supplying the sanitary requirements of India are rudimentary and ineffective.
3. Sanitary reform and progress can be accomplished only by educating, persuading, and empowering the people to adopt measures conducive to health as a detail of domestic and communal life. To that end the State requires an organised establishment, acting under the orders of imperial, provincial, and district authorities to investigate, report, and advise.

PERSONAL HYGIENE.

By S. J. MULLEN, C.M.S.

Srielliputr.

(Continued from page 344, Vol. IX.)

JUST the same as with breathing and the beating of the heart, every step we take and every word we speak wears out or wastes a small portion of our bodies, and this waste is replenished by the food we eat, and which answers several purposes. It also warms us, producing animal heat of which as much is every day generated as would boil a large pot of water; but as the normal heat of our blood is 98.4°F., anything above this must be called fever. Our food gives us strength to perform the various functions of life and thus serves somewhat the same purpose in our bodies as wood or coal does in the railway engine.

Kind of food.—The food of man varies greatly both in different countries and in different seasons in the same

country. Thus in the northern regions, where vegetables will not grow, the natives live entirely on animal food. Many Hindus are pure vegetarians, while others live on a mixed diet.

Composition of food.—Food stuffs are divided into three great classes: the (1) minerals; (2) vegetable; and (3) animal. The mineral includes water, salts, lime and phosphorus, which go to form bones, iron which gives the red color to the blood, and other substances. A few of the animal and vegetable foods may also be divided into three principal kinds: (1) flesh-forming; (2) heat; and (3) strength-giving food. Flesh-forming food contains a large quantity of nitrogen, is spoken of as *nitrogenous food*. Thus pulses, such as peas, dal and gram, contain the largest proportion of flesh-forming food, and more than double that obtained from millet and maize, while rice contains the least out of all the grains. Many a cooly wishing to live like a rich man on rice and ghee, forgets that the raggi, cumboo, cholam, &c., that he was brought up on is much more strengthening. Flesh and fish contain about four times as much flesh-forming food as rice. Non-nitrogenous food stuffs may be sub-divided into three principal classes: (1) fats and oils; (2) sugar; and (3) starch. Rice is composed chiefly of starch, which arrow-root also contains in a purer form. These classes of food are necessary for the body, but they are hurtful if taken solely or in excess. Milk supplies every need for the young in the way of food, as it is the only single article which is sufficient for this purpose; but is unfit to be the sole food of the adult.

The conditions essential to the hygienic suitability of food are: (1) that it should contain all the elementary substances which the body itself includes; (2) that these should be combined into certain form and proportions which experience has shown to be necessary to efficient nutrition; (3) that the total quantity consumed should be sufficient for the wants of the body according to varying circumstances of exertion, climate, &c.; (4) that the classes into which science and experience have taught us to divide aliments should be present in certain definite proportions to each other; (5) that the articles of food should be of such nature as to be suited to the digestive powers of the man or other animal to be fed, and (6) that the food or its mode of administration and preparation, or all combined, should be varied so as to ensure sufficient ingestion and efficient assimilation.

What to eat and avoid.—The poor often eat anything or everything they can afford to get, but many people have some chance in the choice of what they may eat and while a variety of food is best, great care is necessary in its choice as the stomach is the gateway to many diseases, and our food should therefore contain a sufficient proportion of flesh-forming substances. Special care is needed about milk which is very liable to contamination. In Madras milk men sometimes mix sewage water with milk, and to this mixing, very bad fevers as typhoid or enteric fevers have been distinctly traced. Persons who use ghee and sweetmeats in large quantities grow fat and unable to work. They become grey-headed in early manhood and suffer from many diseases. Green vegetables are useful, not so much for their nutritious elements as for the salts

they contain; but they should be well boiled before eaten. Sailors without fresh vegetables are liable to a disease called scurvy. Fruit properly ripe are excellent for dietetic purposes, but if unripe or over-ripe, they are hurtful. The best time to eat fruit is at breakfast or at tiffin. Decayed food of any kind ought to be rejected. Double care is necessary about food when cholera or dysentery prevails, as what may do no harm at other times may then cause sickness and death. Raw fruits and vegetables in large quantities, and all indigestible food, should be avoided. Spices, &c., are useful in moderation, but in excess they injure the stomach. Badly cooked food is unwholesome. People are sometimes made ill through the poison of lead or copper in cooking vessels which should be kept scrupulously clean, and care taken that they are properly tinned from time to time. Food must be regulated partly by the constitution. The English proverb "one man's meat is another man's poison," tells us that food must be regulated by constitutions and idiosyncrasies.

How to eat.—When a woman is boiling rice, she puts the whole of it into the pot at once and at the same time, but if she kept throwing in rice now and then, it would be badly cooked. Just so with our food, which we should eat at fixed hours only, so that the stomach may have time to properly digest one meal before another is taken. The bad habit of giving food to children very frequently should be discontinued, as the majority of the diseases of children is due to over-feeding. Digestion generally takes from 3 to 5 hours. Some articles are digested much more quickly than others. Rice usually takes about one hour, mutton 3 hours, eggs $3\frac{1}{2}$, fowls 4, beans, dal and potatoes $2\frac{1}{2}$, and cabbage 4 hours. Food, especially if hard or tough, should be well chewed or masticated before it is swallowed. The Ex-Premier, Mr. GLADSTONE, was in the habit of giving 32 bites or crumpets to every bit of meat before he finally swallowed it, and used to advise his children to give meat as many bites as they had teeth in their heads. The food is thus mixed with the saliva which has certain properties that help digestion and make the food more nourishing. Water should be only sparingly taken during meals, as too much water dilutes the gastric and intestinal juices, while too little of it interferes with the peristaltic movement of the stomach and thus impedes digestion. Some food taken before going out of a morning strengthens the body and helps to keep off infection, yet some people will persist in going out in the morning with an empty stomach and thus exposing themselves to the risks of fever or cholera. A good warm meal should be taken at noon. Some children attend school situated at at too great a distance to let them come home for meals, they should have a hearty breakfast before they start out. It is very hurtful to be obliged to work on an empty stomach. Children with sufficient food will get on better in their studies. Every school child should have some tiffin and a little food as soon as he or she comes home from school. A good meal should be taken in the evening about 7 o'clock, but eating late at night ought to be avoided. It is good to rest a little after a full meal. Perhaps, more people in the world die from eating too much than from having too little food. The rich often

not to exert. The labor, who are generally undisciplined sometimes injure themselves by overeating when they have the opportunity. We should never burden the stomach. An average adult at average work requires from 10 to 12 lbs. of his own weight of food, including drink in every 24 hours, 8½ ounces of albuminates whether meat or fish, 2½ ounces of fat, including ghee and oil; 14 ounces of starch, including sugar and rice, 1 ounce of salt, including common salt, and those of fruits, and 80 to 100 ounces of water, including coffee and tea; are required for an adult of ordinary laboring capacity.

(To be continued.)

NEW OPERATION FOR CATARACT AT THE CIVIL HOSPITAL, AMRITSAR.*

By RAI BAHADUR, MEHER CHAND, L.M.S.

Amritsar.

THE method described in this paper was first adopted by Dr. MULSONET, of Amritsar, in 1890, and has been followed by me with some slight additions in a very large number of cases.

The operation consists in the removal of the entire lens in its capsule by the manipulation and by lower section, without iridectomy.

The eye having been cocaineised with 4 per cent. solution and washed with 1 in 2,000 parts of corrosive sublimate lotion, the spring speculum is introduced, but not fixed.

The incision in the right eye is performed by standing behind the head, and that in the left eye is done by standing in front, and on the same side of the patient. The incision is made by introducing the point of the linear knife into the corneo-sclerotic junction on the outer side of the globe, on a level with the lower margin of the undilated pupil, the counter-opening being made a little lower on the inner side, and then the incision is completed in the usual way through the cornea.

Pressure is now applied with a flat scoop, or a strabismus hook at the upper border of the cornea, till the edge of the lens presents itself into the incision; by this process the iris, which is often in the way, recedes, and the lens gradually projects, and when nearly half of it is out of the wound, the pressure is withdrawn and the speculum removed. After this, the pressure with the thumb is re-applied to the globe through the upper lid, and counter-pressure applied to the ball of the eye below the wound on the sclerotic coat, with a scoop; the pressure now is very gently and carefully regulated, till two-thirds of the lens come out of the wound. Pressure is now again removed, and the patient is directed to close the eye, and looked towards his feet, when in most of the cases the lens slips out, the iris contracts, the edges of the wound become adjusted, and escape of vitreous is prevented. In cases where expulsion of the lens is retarded, it is completed by the aid of a scoop or a pair of iris forceps.

In those cases where the soft cortical substance of the lens comes out, but a hard nucleus remains behind, the capsule is very liable to rupture, unless tact and patience are exercised, the nucleus also protrudes.

Efficient extraction of the lens, is not of course without risk, which, however, is not so extensive as the old method, which should be cut off by a pair of scissors, instead of wiping it off; a slight escape of vitreous which occasionally occurs is of no consequence, so far as the result is concerned, the patient invariably having good sight.

About 3,400 operations have been performed by this method in the Civil Hospital, Amritsar, out of which nearly one-third was performed by myself.

Removal of entire lens in its capsule, by manipulation by lower segment section, without iridectomy.—The advantages of the lower operation as compared with the upper, are—

1st.—It is easier to do.

2nd.—Spasm of the superior rectus, which invariably results whenever the eye is touched, cannot interfere with the completion of the incision when once the operation is commenced, and also can be disregarded when pressure is applied to remove the lens.

3rd.—Less risk of escape of vitreous, as the lower part of the eye is more exposed to view and more easily manipulated by pressure during the extraction of the lens.

4th.—Spasm of the superior rectus in the upper operation tends to gape the edges of the incision, and so increases risk of escape of vitreous at the time of operation and later on, and, by delaying union, increases the risk of sloughing of the cornea. In the lower operation, no amount of spasm of the superior rectus will cause gaping of the incision, as the incision is at the further end of a segment of another circle, by which I mean the superior rectus being inserted into the sclerotic can act only on that segment of the circle formed by the sclerotic, and only to a slight extent on the neighbouring portion of the segment of the second circle (cornea), and the further removed the incision in the segment of the second circle is, the less the traction, and consequently the less the gaping. We know the eye consists of two segments of different circles, the sclerotic and the cornea. The superior rectus will tend to gape an incision placed anywhere between its ocular attachment and the sclero-corneal junction in front of it; but if the incision be in the cornea itself, the cornea being a segment of another circle, the incision will gape much less than if the cornea were the segment of the same circle, as the sclerotic, and the more we move the incision towards the meridian of the corneal circle, the less the gaping, and once we pass the meridian no gaping can occur. Further, whether the eye is inflamed or over-sensitive, as after an operation it is invariably turned upwards under the upper lid, and we know the upper is very much stronger than the lower lid, and any attempt to press the upper lid upwards with the fingers so as to open the eye cannot be done without pressing on the eyeball. It follows then, that to inspect the incision after an upper operation is far more difficult, and of times positively dangerous, from the pressure used, than when the lower operation is done, in which slight pressure on the lower lid against the malar bone is sufficient to expose the incision.

The advantages of not doing an iridectomy are—

1st.—No instrument is passed into the interior chamber except the linear knife in making the segment incision.

* Being a subject introduced before the Indian Medical Congress and read by the author at the session.

1st.—The iris is not injured, hence there is less chance of subsequent iritis, and consequently less risk of inflammatory action extending to neighbouring structures and endangering the eye.

2nd.—A clear circular mobile pupil, instead of a large gaping irregular pupil, which is not only unsightly, but seriously interferes with clear definite vision.

The advantages of removing the lens entire in its capsule are:—

1st.—It minimizes the changes of iritis supervening, as there are no tags of torn capsule or particles of lens cortical substances present to set up irritation. I find iritis extremely rare, since I commenced removing the cataract in its capsule whereas it frequently results when the lens is removed and the capsule retained, as in the usual operation.

2nd.—There is no necessity for a secondary operation to remove opaque capsule.

3rd.—I have repeatedly seen patients come to the hospital, months after a cataract operation had been performed, in which the lens was removed by opening the capsule by means of a cystotome, complain of blurred vision amounting to marked astigmatism in some cases. The pupil in some cases is clear, the cornea clear and even, and the line of incision almost invisible. If the eye be examined by the direct ophthalmoscopic method, the capsule will be seen, although perfectly transparent, wrinkled into folds. In such cases tearing the capsule across with a needle invariably gives good vision. This wrinkling into folds of a transparent capsule is best seen in those cases in which the capsule is opened by the point of the linear knife when traversing the anterior chamber in making the corneal incision. If the capsule is retained *in situ*, and remains transparent, which can only occur if its attachment to the suspensory ligaments, from which it derives its nourishment, is not destroyed, then it must wrinkle into folds when the eye recovers after the operation, for being non-elastic and not having the support of the lens substance, there is nothing to prevent it from forming folds. Now, this cannot occur when the lens is removed entire in its capsule, and I find, as a matter of fact, that the vision in such cases is clearer and more defined than when the capsule is left behind.

4th.—You can operate on an immature cataract without running the risk of setting up iritis or having to do a second operation, to remove opaque cortical matter and capsule, the objections to operating on an immature cataract. The disadvantages are:—

1st.—Greater skill and more delicate manipulation required, which cannot be acquired by all, and only after much patient practice by some.

2nd.—It is a more difficult operation.

3rd.—Risk of vitreous escaping by misdirected, excessive or unequal pressure during manipulation.

4th.—A slightly larger incision.

5th.—The capsule sometimes bursts when the lens is on the point of escaping, and as in such cases the attachment of the capsule to the suspensory ligament is destroyed, and its source of nourishment cut off, it left behind, it invariably turns opaque and requires subsequent removal. So, if this accident occurs, I always endeavour

to remove the capsule with iris forceps, even at the expense of a slight escape of vitreous; and should it occur, I can generally remove it within the first two or three days after the operation; for I find it better to open the wound and remove it early rather than wait, for its presence invariably sets up iritis and endangers the eye. I am fully convinced the capsule can never undergo complete absorption; it may shrivel up and fall behind the iris so as to be out of the axis of vision, but being fibrous in structure, it can never be completely absorbed. In some cases, at the time of operation, it falls behind the upper part of the iris out of view, and if I fail to grasp and remove it after two or three attempts I leave it, and on the second day after operation I most invariably find it opaque, filling the pupil and easy to remove. I never dilate the pupil with atropine before the operation, as I find by having an active pupil, although there may be a risk of bruising the circular fibres of the iris by the passage of the cataract through the pupil, there is less chance of a bead of vitreous following the cataract, since the iris at once retracts within the anterior chamber as soon the cataract escapes; whereas should the pupil be dilated with atropine it remains prolapsed after the escape of the cataract, and has to be returned into the anterior chamber by a curette or scoop.

A 4 per cent. solution of hydrochlorate of cocaine is instilled three times into the eye, once 10 minutes before the operation, again 5 minutes before, and the third time just before the operation is commenced. After the operation a layer of damp lint soaked in fresh yellow wash is applied, and both eyes fixed with a light muslin bandage without any pad. On the third day the lint and bandage are removed and reapplied, and so on for four days, after which the bandage is discontinued, the pupil dilated with atropine, and a layer of damp lint worn as a screw in front of the eye.

In those cases in which the capsule has burst and is retained, I instil a drop or two of liquor atropine after the operation.

No antiseptics, excepting fresh yellow wash, are used. The eye is washed with boiled distilled water and dressed with yellow wash, and the instruments washed, after each operation, in boiling distilled water.

Generally on the eleventh day the patient is well enough to go out. All are supplied with cataract spectacles before discharge, +11D for distance and +4D for reading, suit the majority of such patients. Poorer patients are given spectacles gratis, and those able to pay can purchase them from the stock in the hospital.

Eight hundred and twenty-four cataract operations were performed in 1892 and 1,145 during 1893 by the new method, and in the current year up to the end of November 1894, 755 operations have been performed, out of which 677 were successful (or about 90 per cent.)

METEOROLOGY.

By R. P. BANERJEE, B.A., G.B.M.S.L.

Medical Officer, Salt Works, Pachbhadra, Rajputana.

(Continued from Vol. VII, page 329).

If a number of bodies heated to different degrees are placed together, it will be found that while those that are the most heated will lose a certain amount of heat (the

their temperature will "fall" those that were the least heated will gain more heat (or rise in temperature), and this rise and fall will continue until all the bodies placed together acquire the same degree of heat, i.e., become of the same temperature.

Heat affects all bodies in some degree or another, and without heat no living thing can exist, nor movement of any sort occur; but though of all chemical forces heat is the most important, still all that meteorology is concerned in is the part it plays on air, watery vapour, mercury and glass; the first three on account of the important place they take in the economy of Nature, and the two latter because most of the instruments are made of, or mounted in, glass and filled with mercury.

Heat however, acts differently on different bodies; thus solids expand cubically or superficially, and are slowest affected, liquids are sooner acted upon and expand in a linear direction; while gases, which are the most easily affected, expand in volume.

Thermometers are instruments for registering and recording the variations of temperatures in solid, liquid and gaseous bodies. Their ordinary form consists of a capillary-bore glass tube, sealed at its upper end, and at the lower extremity provided with a glass bulb filled with mercury or any other liquid, such as alcohol, ether, &c., that is very sensitive to thermal fluctuations. The instrument is graduated by first placing the bulb in melting ice and making a mark which afterwards becomes the zero of the scale. A similar process is enacted by putting the bulb into boiling water to obtain the boiling point, and the space between these two points is divided into an equal number of spaces, each of which is termed a degree, and is further sub-divided into fifths or tenths of a degree. There are three scales in use:—

(a). The *Fahrenheit*, which is in general use for clinical and ordinary purposes and is the English standard of calculation, has its freezing point marked at 32° and its boiling point at 212°. It is divided into 180 degrees, which are further sub-divided into fifths of a degree.

(b). The *Celsius* or *Centigrade* scale, which is graduated from 0° to 100° is divided into 100 degrees and is employed for scientific purposes, and wherever extreme accuracy is desired.

(c). The *Reaumur* scale running for 0° to 80°, though at one time largely referred to, is now seldom used by any one outside of Russia or her dependencies.

In computing calculations or comparing results of various observers, it becomes necessary to bring thermal indications down to the standard of observations, and for this purpose the sub-joined formulae will be invaluable:—

$$\text{Celsius} = (F - 32) \times \frac{5}{9} \text{ or } \frac{5}{9} F \text{ or } R \times 1.25.$$

$$\text{Fahrenheit} = \frac{9}{5} C \times 32 \text{ or } (C \times 1.8) + 32 \text{ or } \frac{9}{5} R \times 32 \text{ or } (R \times 2.25) + 32.$$

$$\text{Reaumur} = \frac{4}{5} (F - 32) \text{ or } \frac{4}{5} C \text{ or } C \times 0.8.$$

There are two ways of reading the thermometer (a). The ordinary method of merely noting the degree on the scale at which the mercurial column remains stationary.

(b) The actual reading in which allowance has to be made for the heat effects on the tube and the contained mercury by adding or deducting, as the case may be, the factor

value for each centigrade degree and the formula becomes $L = \frac{a}{c}$, where L denotes actual length of a degree on the scale; a , the apparent expansion of one degree centigrade; c , the capacity of the bulb and of that portion of the tube below zero and s the sectional area of the tube. Therefore the actual reading above 0°C would be the simple reading minus the factor of expansion for that degree.

Precautions.—(1) Always read to the nearest tenth of a degree. (2) Read quickly and stand as far from the thermometer as is possible, because actual breathing on the tube or radiation of heat from the approaching body are bound to effect the correctness of the readings. (3) Keep the eyes on a level with the top of the mercurial column; because obliquity of vision gives erroneous readings.

Maximum Thermometers, of which there are many shapes and sizes, are merely modified forms of the ordinary thermometer in which the mercurial column is interrupted by an air bulb and the instrument placed in a horizontal position, so that the detached mercury remains at the highest point reached before the remainder of the column recedes. The remote end of this index indicates the degree of heat attained. In some thermometers this index is made of porcelain, and being pushed forward by the expanding mercury is left behind as the latter contracts. After each reading give the thermometer a gentle shake, or two, so as to bring the index down and put it in contact with the mercury in the bulb.

In *Minimum thermometers* the mercury is replaced by spirit of wine, inside which floats a steel index which falls as the spirit contracts and thus records the lowest temperature observed; but when the spirit expands it is too light to float the index, which remains stationary while the spirit proceeds past it. To set the instrument incline the stem till the index falls to the end of the spirit column and replace the thermometer.

Hygrometers are instruments to measure the humidity of the atmosphere, and though for special cases special instruments are devised, still for common use the ordinary maximum and minimum thermometers answer the purpose well enough when their bulbs are covered with a piece of muslin that is moistened with water and not allowed to get dry.

—:O:—

THE GOVERNMENT CINCHONA ENTERPRISE IN SIKKIM.

By G. KING, M.B., LL.D., F.R.S., C.I.E., BARRISTER-AT-LAW.
LIEUT.-COL., I. M. S.

FROM its first introduction to Europe in 1689 by the Countess of Chinchon and her father-confessor down to the year 1820, cinchona-bark used to be administered either in the form of powder or as tincture, infusion or decoction. In 1820 PELLETIER and CAVENTOU separated from the bark the alkaloids, which they named quinine and cinchonine. Quinidine was discovered by HENRY and DELONDRE in 1838, cinchonidine by WINKLER in 1847, and quinamine and aricine found at still later dates. Soon after the separation of the two alkaloids first mentioned, it was found that, in medical practice, far better results were obtained from

*Being a paper read before the Indian Medical Congress and sent to the Record for publication.

there was then from the exhibition of any of the pharmaceutical preparations of bark hitherto employed. What was called quinine in these early days was, no doubt, a mixture of all the alkaloïds contained in the bark used in its manufacture. The new drug was admitted into the Pharmacopœia under the name of quinine, and it is only in comparatively recent times that the other alkaloïds were even mentioned in the Pharmacopœia far less admitted as official.

The medicinal cinchona trees are all natives of the great forests of the Andes of South America. As the consumption of their barks extended in Europe, the trees in the Andes gradually began to disappear, the bark-cutters leaving year by year to explore forests more and more remote from the coast, and no system of conservancy was ever enforced by the various Governments in whose territories the trees occur. The result of all this was that the price of cinchona-bark steadily increased, and as the demand for it also increased, serious fears began to be entertained of the complete extinction of cinchona in its home in South America. The Government of India have, for many years, been the largest consumers of febrifuges in the world; and the Dutch Government were also, by reason of their Malayan possessions, much interested in the bark trade. These Governments were accordingly the first to take any action to avert the impending calamity. The suggestion to introduce the medicinal cinchonas to the hill ranges of British India was first made in the year 1835 (i.e. fifty-nine years ago) by Dr. FORBES ROYLE, a Member of the Indian Medical Service. Dr. ROYLE was at that time Superintendent of the Hon'ble Company's Garden at Saharanpur. In the years 1847, 1853 and 1856, Dr. ROYLE repeated his suggestions, but no action was taken upon them. In 1850 Dr. GRANT, then the Hon'ble Company's Apothecary-General in Calcutta, took the matter up, but without result. In 1851 Dr. FALCONER, who was the Superintendent of the Calcutta Botanical Gardens, again brought it forward; but also ineffectually. Dr. FALCONER's successors at the Botanic Garden, Dr. T. THOMPSON and Dr. T. ANDERSON, also both successively pressed it on the attention of Government and in 1858 active measures were at last taken which resulted in the establishment in 1861 of cinchona plantations in the Nilgiri Hills and in British Sikkim, near Darjeeling. A little before this the Dutch Government had also begun plantations in Java. As soon as the trees thus established in British India began to yield seed, that seed was freely distributed to all applicants, with the result that, before many years had elapsed, not only had the Government plantations been greatly increased, but thousands of acres in the hill ranges of Southern India and in the uplands of Ceylon had been covered with cinchona trees by the enterprise and energy of private planters.

Soon after their plantations began to yield bark in sufficient quantity, the Government set about discovering the best mode of utilising it. The first bark to be dealt with was red bark, the produce of *Cinchona succubra*. This species had proved much more easy of propagation and a much faster grower than the species which are *per excellence*, quinine-barks. Red bark, although rich in

its yield of total alkaloïds, is not proportionately rich in quinine, and is never chosen as a bark from which to manufacture that drug. With the view of making the most of the red bark of which they had become possessed, Government appointed a commission of medical officers to test the respective values as febrifuges of the alkaloïds which are found in *succubra* bark. The result of these experiments was to prove that, while quinine is the best febrifuge, cinchonidine and cinchonine have also much value. Government therefore resolved on the issue of a preparation which should contain all the alkaloïds of red bark in the exact proportion in which they naturally occur in it. The preparation which resulted is the well-known cinchona-febrifuge. When this preparation was subjected to analysis, it was proved to contain, besides the three crystallizable alkaloïds just named, an uncrystallizable alkaloïd, the existence of which in cinchona-bark had not previously been suspected. This alkaloïd still remains without any other name than the *amorphous alkaloïd*. It is a far more powerful febrifuge than quinine, a quarter of a grain of it being a sufficient dose for an adult. But it possesses depressing and nauseating properties which prevent its use in an uncombined form as a medicine. There is no doubt, however, that it is the presence, in small proportion, of this alkaloïd in cinchona febrifuge which makes that drug a remedy for fever equally powerful with quinine, although rather more unpleasant. When cinchona febrifuge was first issued for use in Government hospitals and dispensaries, it was subjected to much hostile criticism, the value of some of which is well illustrated by two examples:—One medical officer, whose report I perused, declared against the use of the drug, because he said he had found it inert; and, if I remember rightly, he declared that he would as soon treat his fever patients with wheaton flour as with cinchona febrifuge. Another officer, whose report I also read, excused himself from using or recommending others to use the drug on the ground that it is an *active poison*. I cannot myself offer any experimental evidence as to the value of cinchona febrifuge. The question has long ago been practically settled in favor of the drug, and the controversy need not be re-opened. Moreover, it is still being bought by private persons who are under no sort of compulsion to use it.

Cinchona febrifuge was first begun to be made in the Sikkim plantation during the official year 1874-75, but during that year only 48 pounds of it were issued to Government hospitals. During the year 1875-76, 1,940 pounds of it were given out; and its consumption increased so materially that, up to the end of the year 1887-88, no less than 87,704 pounds of it had been issued from the factory at Mungpoo. The whole of this large quantity was issued and was consumed in substitution of quinine. And it may be of interest to compare the cost of this quantity of the drug with that of an equal quantity of quinine. Cinchona febrifuge during the whole of the period just mentioned, was sold to Government officers and to all charitable institutions at the uniform rate of one rupee per ounce. Quinine, as is well known, fluctuates greatly in price.

According to the Government's estimate, the quantity of quinine consumed in India during the year 1901-2, the average year of the Indian war, was 8,000,000 lbs., was eight shillings and four pence per cwt. per cwt. The sterling value of 8,000,000 lbs. of quinine would, at this rate, have been £1,280,000, but the actual cost to the Indian consumer was only £1,000,000, the favorable rates of exchange which prevailed during those years, have been a good deal more. The actual cost to the Indian consumer of the febrifuge, which took the place of this quantity of quinine, was Rs. 14,47,116. The saving, therefore, was very great, and was sufficient to cover the total cost of the plantation four times over and to leave the Government in possession of an estate from which ten thousand pounds of quinine and cinchona febrifuge can annually be turned out.

For ascertaining the value of cinchona bark, I have been fortunate enough to find that which has of late years been sold in the value of quinine. According to a letter which has been furnished to me by our worthy Assistant Surgeon-Colonel R. HAARVEY, the average price of quinine in London during the year 1870 was, as stated by the London shillings and two pence per ounce. From that year it gradually declined until, in 1887, it had fallen to about two shillings per ounce. During these years, as I have already shown, the Indian consumer was able to supply himself with cinchona febrifuge at the uniform rate of one rupee per ounce. The ultimate cause of the great fall in the price of quinine was the action of the Indian Government in distributing cinchona seed in the most liberal manner to all who might apply for it. With the seed thus freely received the planters of Ceylon almost covered with cinchona trees the coffee plantations of that island which had been devastated by the fangoid pest *Hemileia vastatrix*. When the plantations thus too extensively put out came into bearing, the exports of bark from Ceylon became so enormous that the South American export of bark was completely swamped, and prices fell to a quite unremunerative limit. The fall thus brought about has been maintained, until the present time, not so much by exports from Ceylon, which are rapidly diminishing, as by exports from the large tracts of land in Java, which, in a similar manner, had been covered with cinchona trees by planters who had been supplied with seed from the plantations of the Dutch Government in the Preanger Residency.

One matter of importance in this connection is too apt to be overlooked, and that is that the Government quinine is *de puris* as it can be made, whereas much of the quinine sold in the bazars, and especially in the bazars in the *confines*, is sophisticated with other alkaloids, and even with substances of less objectionable character. I have myself seen a sample of quinine obtained in the *market* which consisted of flour flavoured with some bitter substance.

But the crowning advantage of the Government Quinine Factory to the people of India is that it has enabled Government to introduce the system of selling at every village post office pure quinine in packets containing five grains at the cost of one pice—a pice being at present exchange rates equal to a good deal less than one farthing sterling. By this step the Government appears to me to have at last realized what they avowed to be their object when they first entered in the cinchona enterprise, *viz.*, "to put the only efficient medicine for the most fatal disease in the Indian Empire within the reach of its poorest inhabitant."

—:—

CLINICAL REMARKS ON THE PYREXIAL STATE.

By SURGEON-CAPTAIN PATRICK HEHIR, M.D., F.R.S.E.,
F.R.C.S.E., D.P.H. Cantab.

*Lecturer on Medicine and Pathology, Hyderabad
Medical School.*

In endeavouring to find out the cause of the fever, we should be careful not to mistake some complication arising incidentally (that of tubercular meningitis, in cases of pulmonary phthisis, of septic inflammation of internal organs from malignant endocarditis of acute bronchitis occurring in enteric fever, etc.) for the primary disease. If there is any doubt, whatever, the observer may relieve his uncertainty by noting whether the supposed cause is enough to give rise to the amount and character of the fever which is present. The pyrexia arising from the specific contagious or infectious diseases embrace a wide field. In this class the diagnosis is comparatively easy when the disease is fully developed, but the physician, who is thoroughly acquainted with the special characters of all the infectious diseases, especially those of the pre-eruptive period, is not likely to fall into error in making a diagnosis. If the pyrexial state is primary, that is unconnected with any local life to produce it or explain its existence, the state is termed "a fever" or a specific, idiopathic, primary or essential fever. In such a fever the blood is believed to be primarily affected by the poison entering into its substance, and for the following reasons:—

(1). A period of incubation indicates the time when the introduction of some specific poison has taken place. (2). The fact that such fevers run a definite course, during which time a very great destruction of tissues takes place, by the decomposition of which, in the absence of food, various substances of unstable chemical composition are formed, and which are attended with a rise in the temperature of the blood. The muscles, the structures of the nervous system, the osseous system, and the red blood corpuscles waste away, while little or no fresh material is assimilated to compensate for the loss. At the same time excreta may be either excessively eliminated, diminished in quantity or

absolutely retained in the system, the products of metamorphosis circulating in the blood—a retrograde metamorphosis, which is increased by the accelerated action of the heart. In such cases critical discharges may occur at the close of the fever, or serious complications may occur during the course of the fever. Its type may assume a dangerous character, becoming typhoid, or ataxic, or malignant. Local complications may also occur especially in the form of inflammation of solid organs, effusions in the joints, abscesses, and the like, which are sometimes called the "dugs of the fever." All these diseases are due to the introduction of a foreign living poison into the system which, after gaining access to the body, remains latent for a certain time, this period of clinical inactivity being known as the period of incubation. The period at which the symptoms manifest themselves after exposure to contagion is of importance for the purposes of diagnosis; for the duration of the latent period or the period of incubation varies with the nature of the disease; probably also with the dose of the poison, and the channel through which it is introduced into the body. After the latent period is elapsed, the disease manifests itself; usually lasts for a definite time; and then ends either in recovery or death. In many of the true specific contagious diseases, characteristic skin eruptions or rashes, which appear at definite periods of the disease, and on definite parts of the body, are observed; these rashes are consequently of great importance in diagnosis. In many there are characteristic local lesions, such as the sore throat of scarlet fever; the ulceration of the intestine of typhoid. Another point which is characteristic of most of these fevers is, that one attack usually protects against a second; as a rule therefore the true specific contagious disease only occurs once in a life-time. Some of them are more common at one period of life than at another, the exanthemata, for example, are usually contracted during childhood. Scarlet fever is rarely met with in infants under twelve months old; typhus is more common in adults than in children, etc. When a fever is considered to be one of the specific type, the attention of the physician should be directed to the following points:—

The presence of a rash; its exact character and distribution; the date of its appearance. The physician must remember that a rash is not always present, even in those diseases which are usually characterized by it. Scarlatina line eruption for instance are not very uncommon; the rash, too, may have disappeared before the case came under observation. In calculating the time at which a rash ought to appear, due allowance must be made for variations in the latent period which seem to occur, and for the difficulty that there is in fixing the exact date of exposure to infection, and the exact date at which the attack commenced. Care must be taken not to confound the eruption due to skin diseases or to drugs (both of which may of course be complicated with pyrexia) with the rashes of fevers.

If we suspect the case to be one of true specific contagious disease, look for a rash and for the symptoms and the signs indicative of the characteristic local lesion; see whether the height of the temperature and the period of incubation are in keeping with the supposed nature of the

case; ascertain if the patient has been exposed to infection; if there are similar cases in the house or neighbourhood; if he has previously suffered from the suspected disease, etc.

When you cannot make a diagnosis at the first visit, isolate the patient and take precautions to prevent the spread of infection in case the pyrexia should be due to an infectious or contagious disease.

The presence of characteristic symptoms and physical signs (other than the skin eruption, just referred to) such for example as the early bronchitis of measles; the bone aches in dengue; severe backache, headache, vomiting, prostration, sweating in small-pox, the diarrhoea, slight fulness of the abdomen, tenderness and gurgling in the right iliac fossa, and the enlarged spleen of enteric fever and so on.

There are other points also which, in doubtful cases, carry great weight in arriving at a definite conclusion, such as history of contagion, of exposure to an obvious source of infection, the date of such exposure, the length of time which has elapsed before the onset of the disease, the appearance of the rash, and other characteristic symptoms; the presence of other cases of illness in the same family or house; the prevalence of an epidemic in the neighbourhood, or in the part of the country in which the patient has been living.

When the exact source of infection is not clear, the drainage of the house in which the patient has been living, the source and character of the water and milk supply, and any other possible sources of infection must be investigated."

The history of a previous attack has its importance, for these diseases seldom occur twice. Although one attack protects, as a rule, against a second, this is by no means always the case, and some people possess the unfortunate idiosyncrasy of again and again contracting the same specific contagious disease (typhus, for example) whenever they are exposed to the contagion. The author remembers the case of a West Indian negro, who was admitted in the height of and suffering from an attack of hæmorrhagic small-pox, whilst his body was "pitted" all over with pock marks. Such cases are, however, rare, or at least much less common than is popularly supposed to be the case. The thermometrics of the various specific infectious fevers are peculiar, each differing from the other in some way or other, to thus form an important guide to their mode of development, and the course they follow. The different specific contagious diseases have distinct, and for the most part characteristic temperature charts—for example, the mode of development and the whole course of the temperature in typhoid, typhus and relapsing fever. The behaviour of the temperature, when rash appears, is a point of some importance. In some diseases—small-pox for instance—there is a decided fall in temperature when the rash appears.

In short, then, the main points which should strike the physician in investigating a case of one of these infectious fevers are:—

- (1) The character of symptoms and their mode of development.
- (2) The nature of the physical signs.

(3) The exact state of the attack and its mode of commencement.

(4) The temperature; its height, mode of development and course.

(5) A history of exposure to the infection and the duration of the supposed period of incubation.

(6) The history of a previous attack of the infections or contagious disease, from which, it is supposed, the patient is suffering.

(7) The age of the patient.

To us practising in India, by far the most important types of fever are those due to malarial poisoning and the main points of indication in them are:—

The periodicity of the pyrexial attacks; the character of the temperature curve (sudden rise, short duration and rapid fall) and the presence of a distinct cold, hot and sweating stage. In some cases the paroxysm of fever occurs every day (quotidian); in others, every other day (tertian); in others every fourth day (quartan); mixed types, such as double tertian, double quartan, etc.; are also met with. As a rule, the attacks of fever occur at the same time of day; in some cases, more especially at the commencement of the disease, the usual time of occurrence is anticipated, instead, for example, of occurring at 12 o'clock each day, quotidian ague may occur on Monday, say, at 12, on Thursday at 11-45, on Wednesday at 11-30, and so on; in cases of this description the fever is said to be wasting. In other cases, the period of occurrence is postponed (Monday 12, Tuesday at 12-15, Wednesday at 12-30, and so on) the fever is then said to be waning.

The duration of the disease is a further point of great significance. Thus malarial fevers, when untreated, may continue recovering for a considerable period; as they have no fixed and definite duration; and even when quinine and other appropriate remedies have been vigorously administered, the fever poison may remain lurking in the system (possibly in the spleen, liver, pia mater, or in the red marrow of the bones) and a paroxysm of fever may come on some months or even years after the first attack of the disease.

Add to the foregoing the fact that in all such cases there is the history of exposure to malaria in some previous period and the evidence is almost conclusive.

As ague is exceedingly common in India the occupation and the residence of the patient (whether he has lived in a malarious district) should always be carefully investigated.

The state of the patient between the paroxysms of ague, the conditions of the spleen, the character of the blood, are all deserving of special attention, and upon the best alone of these a diagnosis may often be made. After the paroxysm passes off, the patient is, as a rule, free from fever and the temperature may, for a time be, subnormal, there is perhaps some lassitude and fatigue, but the patient may otherwise feel well. After repeated attacks the patient is apt to become anæmic and cachectic. During the febrile attacks the spleen increases in size, and after repeated attacks a chronic enlargement of the organ (which has been termed ague-cake) may be established. During an attack of intermittent fever, the red blood

corpuscles undergo a marked diminution; the white globules are usually in excess; pigment granules can often be seen in the blood; and a polymorphic organism, the *plasmodium malaria*, can be demonstrated.

When the pyrexia forms a local inflammation the more salient points to fix one's attention on are:—The presence or absence of any local pain, symptoms of derangement of function of some particular part or organ. Thus at the beginning of an attack of acute pleuritis a sharp, shooting pain in the side, which catches the breath and prevents deep inspiration, is usually a prominent symptom. As a rule, there is a short, dry cough; and the respiration is rapid and shallow. All inflammations, however, are not accompanied with pain. The liver, lung, peritoneum, the nerve centres of brain and spinal cord, and other parts may be extensively inflamed without pain being felt. Hence the special care required in every case where the causes of the pyrexia are not obvious, is the careful examination, by physical and other means of all the internal organs, more especially the kidneys, liver, heart and lungs. We have seen very grave mistakes made in some cases, and it is a regrettable matter that in some the mistakes were of such a nature, that the least care would have eliminated them. The deeper inflammations of the liver are especially liable to be overlooked. Dr. MURCHISON states that in many cases of inflammation of the substance of the liver there is no fever, and when the inflammation is chiefly confined interior to the substance of the organ, pain is absent; but when the capsule, to which the sensory nerves are abundantly distributed, is affected, either by direct implication by the inflammatory process, or by being suddenly put upon the stretch by internal pressure, pain is usually a very prominent symptom.

The presence of abnormal physical signs at the seat of the disease is another point deserving of investigation in localised inflammations. The exact nature of the physical signs, which characterise inflammation of the different internal organs must be known, and if any are present, their proper value must be given them.

Even in localised inflammations the character of the temperature is deserving of note: for in the majority of the acute cases we note that the pyrexia is of the nature we have described in the continued type of fevers. An exception, however, is seen in inflammatory diseases which are attended with suppuration, i.e., the production of pus, or suppurative inflammation.

If you suspect a septic fever, look for an external wound or injury, or other (internal) source of infection; and regard the temperature curve and the general symptoms.

If you suspect the presence of a local inflammation, make a careful physical examination of the organ or part, and ascertain if there is any pain, or if there are any indications of functional derangement.

In all obscure cases of pyrexia, the condition of all the viscera, but more especially of the lungs and liver, must be carefully investigated.

In a case of unknown origin the course to pursue is as follows:—Note the temperature, the general state of the case, and make a scrutinising examination of all the symptoms and of the organs of the body. This duty having been

considerably carried out, the physician must abide the course of events, carefully watching the development of the symptoms which will, as a rule, even at an early stage, enable him to arrive at a definite decision as to the nature of the case.

In cases of imposture or malingering we have to be prepared for the tricks of palats who are often very clever in this kind of deception. The physician must (1) satisfy himself that the increased temperature is genuine. He must see that no external source of heat, such as a hot bottle, poultice, etc., is in contact with the patient; and must take care that the elevation of the mercury is not the result of friction; for it has been suggested that the extraordinary elevation of temperature, which has been observed in some hysterical cases, may possibly have been produced by the patient rubbing the arm against the bulb of the thermometer. The physician should himself hold the thermometer in situ while the observation is being made, and should take the temperature not only in the axilla, but also in the mouth and rectum. The general condition of the patient at the time of the observation and the condition of the part (such as the axilla) with which the mercury is in contact, should be carefully tested. In rare instances there may be very great rise of temperature without any malingering. These are the so-called paradoxical temperatures, always hitherto met with in hysterical females. The chief means of diagnosing these are a history of neuromyosmes, together with the extraordinary character of the temperature curve. The remarkable height to which the temperature may rise, and the sudden variations which occur together with the absence of grave symptoms, in many cases show conclusively the nature of the case.

Having satisfied himself that the elevation of temperature is genuine, and that there is no obvious cause of pyrexia present, he may, by the method of exclusion, be able to conclude that the pyrexia is due to derangement of the nervous system.

For the next step in the diagnosis, he must rely upon his knowledge of nervous disease. Provided that there is no distinct evidence of organic disease and granting that there are symptoms of functional derangement (such as hysterical symptoms), he may feel compelled to conclude that the pyrexia is due to a temporary and functional disturbance of the nervous mechanism concerned in the production and regulation of the animal heat. DR. BYROM BRAMWELL says:—

For my own part I see no reason why such functional and temporary derangements may not occur. Hysterical paralysis, hysterical contracture, hysterical anaesthesia, hysterical dyspnoea, hysterical palpitation, are all well recognised conditions which, like hysterical pyrexia, are, I think, probably due to arrested blood supply, a spasmodic arterial contraction, shutting off the nutrient material from certain of the cerebral nerve centres connected with the motor, sensory, respiratory, cardiac, heat-producing or heat-regulating mechanisms respectively. It must, however, be stated that cases in which a diagnosis of hysterical pyrexia is warranted, are rare. Cases of the kind to which DR. DONKIN has applied the term

'paradoxical temperature,' are of the greatest interest, and require much more careful study than has as yet been given to them. They are calculated, I think, to throw some light upon the position and structure of the nervous mechanism concerned in the production and regulation of animal heat.

It is a good rule which states in hyperpyretic temperatures without grave symptoms, to suspect relapsing fever, or malingering.

When you feel satisfied that the pyrexia is genuine, and that it is not due to a local inflammation, specific, contagious, malarial or septic disease, and when there are nervous symptoms present, you may conclude that the fever results from the nervous lesion.

The differential diagnosis of the exact nature and position of the nervous lesion, and whether it is functional or organic, can only be determined by a careful and detailed examination of the nervous system, and depends on considerations which it would be out of place to consider here.

A MIRROR OF PRACTICE.

A CASE OF UNCOMPLICATED MULTILOCULAR OVARIAN CYST: OVARIOTOMY: DEATH FROM SHOCK.

By EDWARD E. BALM, C.M.S. (Hyderabad.)
District Surgeon, Parbhani.

SUNTHU, a Hindu female *æt.* 45, was admitted into my dispensary with an abdominal tumour, on the 11th September 1895.

Previous History.—Stated that she had had a miscarriage of a four months' fetus about a year and six months ago, after which she noticed a swelling, about the size of an orange above the pubes, this gradually increased in size, and was accompanied with pain. About three months later, a similar swelling commenced in the right side. She had been suffering great pain for the last four months. Since the miscarriage there has been a constant and profuse bloody discharge.

Present Condition.—The patient is very thin, weak and anæmic. A tumour about the size of a cocoanut, tense, hard and immovable, occupies the hypogastric region. A second one, about as big as an orange, lies in the right iliac fossa. There is a double semi-solid cyst in the right lumbar region, extending to the right hypochondriac region, which is adherent above. The os uteri is contracted, and there is a free bloody discharge per vaginam. Intense pain is complained of in the hypogastric growth. On examination per rectum, the tumour is found to be hard and pressing against the bowel.

Diagnosis.—Ovarian cyst.

Treatment.—The patient was kept on tonics and strengthening food for about a fortnight previous to the operation. On the day of the operation the bowels were emptied by an enema and the bladder by a catheter.

Ovariectomy.—An incision, about 8½ inches in length, was made in the linea alba. After a complete dissection, the peritoneum was reached; this being laid open, it was found that the first cyst was free from adhesions; the fluid was

then emptied. The cyst in the hypochondriac region was a little adherent above to the liver. Seven quarts of fluid were removed from this cyst. The pedicle was ligatured with catgut and about an ounce of blood was lost at this time.

The abdominal cavity was washed with a warm solution of borax, then with a solution of carbolic acid (1—100). The edges of the wound were now brought together with double cyanide of mercury dressing.

After the operation collapse set in, and though ether was given subcutaneously and ram by the mouth, the patient died from shock within four hours of the operation.

Remarks.—This case might have been mistaken for one of cancer of the uterus, combined with an ovarian cyst, from the tense, almost immovable mass pressing against the bladder, uterus and rectum; also from the acute lancinating pain and the constant and profuse discharge of blood from the uterus.

The whole operation was extremely simple, and was done most carefully under strict antiseptic precautions, but the stage at which the patient sought relief was hopeless, as she was very emaciated and weak from the profuse loss of blood and the constant pain. I declined at first to operate, but at the persuasion of the woman and her husband I consented to undertake it.

A CURIOUS CASE OF TRANSPOSITION OF THE VISCERA.

By MICHAEL TINDALE, C. M. S.
Chin Chin.

ZUFARSHAH, a Mahomedan Fakir, aged 21, consulted me with regard to treatment for an enlarged spleen.

On examination, I found an enlargement, obliquely situated, and occupying the right hypochondriac, right lumbar and part of the right iliac and umbilical regions. On percussion the enlargement was found to extend from the 6th intercostal space to within 2 inches of the anterior superior iliac spine, feeling along the anterior border of the enlargement, I discovered the characteristic notch 1 inch below the right costal arch, which placed beyond doubt the fact that the spleen was situated on the right.

This excited my curiosity, and I examined the other organs. To my surprise I felt the apex beat of the heart 1 inch below and ½ inch to the left of the right nipple. On percussion a dull note was elicited in the 4th, 5th and 6th intercostal spaces on the right side, while the note was quite resonant on the left. On auscultation the heart sounds were heard on the right side.

On examining the liver, I found its round, smooth margin below the left costal arch.

The above clearly shows that this man's spleen and heart were on the right side and the liver on the left—a condition which, I believe, is rarely met with.

A RARE CASE OF FUNGATING BUBOES.

By K. K. VELU, C.M.S.,
Calicut.

SAUKARM, a Hindu male aged 27, was admitted into the Civil Dispensary, Calicut, on the 29th of January 1895.

Previous history.—Had suffered from gonorrhoea about four years ago. About 6 months previous to his admission he had had a swelling in both groins, which suppurated, leaving indurated ulcers.

Present state.—Fungating buboes in both groins. No pyrexia. Internal organs normal.

Treatment.—Cromic acid solution was freely applied and the parts were poulticed. This was repeated on the fourth day, but it had no effect. On the eighth day the patient was put under chloroform, and the whole mass removed by wire excisor by Surgeon-Major H. C. CARRUTHERS, after it had been removed, the surface was freely cauterized and a poultice applied. This treatment answered remarkably well and in a fortnight's time the patient was fit to be discharged.

—:—

A MUMMIFIED FOUR-MONTH TWIN-FŒTUS RETAINED IN UTERO TILL FULL TERM OF THE OTHER TWIN.

By Z. FELDSTEIN, M.D. (Univ. of New York).

Calcutta.

On the 2nd August 1895 I was called to see Mrs. B., a European lady, of about 38 years of age, the mother of seven children, who was in labor. The nurse in attendance who sent for me, stated that the pains had been on for

refreshed and with pains coming on. I douched the passage with a solution of mercuric chloride and after thoroughly disinfecting my hands in the same solution, I endeavoured to help nature to dilate the os by digital expansion. This served admirably; for in a few minutes there was complete dilatation. The head descended; so I ruptured the membranes, and shortly afterwards with a few good uterine contractions a full-term healthy male child was expelled. Finding that the uterus failed to expell the placenta after waiting half an hour, I again disinfected my hand and passed it up into the uterus. Observing that there was a pretty free bleeding, and that the placenta was not only adherent, but presented a peculiar nodular mass near its centre, I sent for Dr. JAMES R. WALLACE to assist me. On examining the patient, he said the mass was probably a polypus or an aborted mummified twin fœtus. He carefully detached the placenta, and when it was removed, we found within a separate membrane of its own, a mummified four-months' fœtus, having its own separate shrivelled placenta within the sac that surrounded the fœtus. An illustration of the mummified fœtus with its placenta is shown in the diagram here given. The patient suffered from fever for a few days, which was probably due to enlarged and painful breasts, as no indication of any septic trouble from impure lochia showed itself. In connection with the death of the twin fœtus in utero, it is

nearly 40 hours, that the os was almost fully dilated, but that all further uterine action had ceased for four hours. The patient seemed somewhat exhausted and restless, and on vaginal examination, I found the os dilated to the extent of four fingers. There was no rigidity of the cervix, and the uterus itself seemed flabby. I administered a dose of chloral and ergot with ammonia. Within half an hour the patient slept, and awoke an hour later

note worthy to recall the fact, that the patient distinctly remembered that when she was about four months pregnant she slipped in her bathroom and fell. For a couple of days afterwards she lost a little blood per vaginam. She suffered in no other way, and went on to full term. Undoubtedly the fall resulted in the death of the twin fœtus which in every respect exhibited a most perfect mummification.

OUR PICTURE GALLERY.

MOHENDRA NATH OHDEDAR, RAI
BAHADUR, L.M.S.

THE subject of "Our Picture Gallery" sketch, Rai Bahadur M. N. OHDEDAR, was born at Sripur, District Khulna, on 7th January 1856, and when a boy of five, went to Benares, where his father, the late Dr. KALI NATH OHDEDAR, was Assistant Surgeon in charge of the Government Dispensary. He received his primary education partly in the Queen's College, and partly in the Jai Narain's College at Benares. In 1871 he entered the Canning College at Lucknow, and from there passed the Calcutta University Entrance Examination in 1872 and the First Arts in 1874, when he entered the Lahore Medical College, where he received a Government scholarship. In the general educational department, English literature and history were his favorite subjects, but his dislike to mathematics, which was his bugbear, made him leave College at Lucknow and make up his mind to select a profession. He was originally destined for the bar, but the respect that his father commanded at Benares, the high estimation he was held in as a medical man, prompted his son to follow his father's footsteps, which desire was further incited by his having, during school vacations, frequently accompanied his father to the hospital, where he took a pleasure in watching the dextrous mode in which surgical operations were there performed by him.

In the Medical College at Lahore, he scored *high marks* at the first L. M. S. Examination, and obtained the first prize in Anatomy. Passing the second L. M. S. Examination in July 1879, he received the first prizes in Medicine and Midwifery and stood second in order of merit. He entered Government service on 1st August 1879 as a supernumerary Assistant Surgeon, and was attached to the Medical College Hospital at Lahore. Two months later his services were placed at the disposal of the Government of N.-W. P. and Oudh, where his first substantive appointment, was the medical charge of the Pilgrim Hospital at Srinagar, in Gurhwal. This town was washed away the other day by the overflowing of the Gohna Lake. For some reason or other, this hospital was so unpopular with the hill people, that no surgical operation of any importance had been performed for some months past. The following true copy of a report on the hospital by Brigade-Surgeon W. WATSON, M.D., dated 1st December 1881, to the Senior Assistant Commissioner, Garhwal, will give some idea of the state of affairs at that time:— I have the honor to report for the information of the Commissioner of the Division that I have inspected the dispensaries of Srinagar, Karnpryag and Gansal on behalf of the Surgeon-General N.-W. P. and Oudh. I was exceedingly struck by the improvement in the management of the Srinagar Dispensary under Assistant Surgeon MOHENDRA NATH OHDEDAR. When I last saw the Srinagar Dispensary in 1879, I found that not a single important operation had been performed for months past.

Assistant Surgeon MOHENDRA NATH OHDEDAR is popular

in this place and with his subordinates, and is doing excellent surgical work. He showed me two cases on whom he had operated one a successful operation for stone in the bladder, the other a case where he had stretched the ulnar nerve for leprosy of the hand. He also showed me two old cases operated on sometime ago. One excision of the knee joint in a boy, the other operation for cataract in an old man. Both were very successful. The old man saw well and the boy walked on crutches."

The operation for extraction of cataract had never been performed at that hospital, and being young and enthusiastic, Dr. OHDEDAR thought that a few successful operations on the eye would go a long way towards gaining the confidence of the public and raising the popularity of the hospital. The first few cases operated on by him were fortunately successful, and SIR HENRY RAMSAY, who was then Commissioner of the Kumaun Division, was so pleased at this success that he suggested that Dr. OHDEDAR should be appointed Superintendent of all the Pilgrim Dispensaries in Garhwal and Kumaun on a pay of Rs. 300 per mensem and travelling expenses, but this proposal somehow fell through. He applied for and obtained privilege leave (from 7th August 1882 to 9th October 1892) and fully intended giving up service and settling down as a private practitioner if he was not posted to a good station on the expiry of this leave. While on leave, he received orders from Dr. CHRISTISON, Inspector-General of Hospitals, to take charge of Maharaja Vizianagram's Hospital at Benares—the station where his father had been an Assistant Surgeon for over 17 years. He took charge of this hospital on 10th October 1882, and while serving under Surgeon-Colonel W. HOOPER, who is now Surgeon to the India Council, he attracted the attention of Dr. W. WALKER (Inspector-General of Hospitals in these Provinces), and was transferred from Benares to Allahabad, where he was placed in charge of the Female Department of the Colvin Hospital on 25th January 1884. Passing his first septennial examination he was gazetted a second grade Assistant Surgeon on 1st August 1886, and an order of Government of these provinces exempted him from the operations of the "Arms Act." On 23rd January 1893 he was created a Rai Bahadur as a personal distinction, and on passing the second septennial examination he was promoted to the first grade on 1st August 1893.

During these ten years at Allahabad he served under many Civil Surgeons, among whom were Drs. J. OLEGHORN, A. CAMERON, and J. McDONAGHY ANDERSON, FREYER, MACLAREN and HAWKINS; and he secured the good will of all these officers, even though unfortunately he was unable to show an annual return of five or six hundred major operations, among which (in these provinces) operations on the eye are the largest in number but as there is a separate Eye Hospital in Allahabad under the management of Surgeon Lieutenant-Colonel G. C. HALL, an officer with a provincial reputation—to whom the majority of eye-cases go for treatment, there are not many cases left for any one else. Still there are a few Assistant Surgeons in these provinces who can show a record of half-a-dozen or more successful excisions of the upper jaw for sarcoma or of the

Yours very sincerely
M. N. Choudhary

tongue for epithelioma. DR. OHDEKAR is the only Assistant Surgeon in that part of the country who has performed ovariectomy—and though he may show fewer operations on the eye than can other Assistant Surgeons in those provinces, he has not been idle, as is shown by a big list of his general surgical work.

Early in the year 1888 the local Dufferin Committee appointed him their Honorary Secretary, and under his care the Dufferin Fund of Allahabad was very well managed. The Hospital which is under the charge of a Lady Doctor, has become so popular, that in his speech at the opening of the present Dufferin Hospital, on 16th February 1891, SIR AUCKLAND COLVIN spoke of DR. OHDEKAR and his work in very complimentary terms. The gist of the speech was published in the *Pioneer* and the *Morning Post*. The following copy of a letter from SIR AUCKLAND COLVIN, the late Lieutenant Governor of these Provinces, speaks for itself:—

DEAR DR. OHDEKAR,—I write a line to express to you my great pleasure at the Viceroy having agreed to accept my recommendation that you should receive the distinction of Rai Bahadur, which was notified in Saturday's *Gazette*.

"Your labors in the interests of your countrymen and women deserve a better recognition than that which the Government can give them; and personally it is a source of great gratification to me to have been able to give you proof of my strong sense of your services on behalf of the Dufferin Association." Yours sincerely, AUCKLAND COLVIN.

In connection with the Allahabad Dufferin scheme there is a class attached to the Dufferin Hospital for training midwives, nurses and compounders, to whom DR. OHDEKAR had to lecture for an hour every day, and for their use he published a book on Midwifery which was written in Urdu, and after being reviewed at the request of the Provincial Dufferin Committee, N. W. P., was very favorably reported on by Surgeon-Colonel RICHARDSON, Inspector-General of Hospitals. He did not receive any remuneration from the Fund for teaching the girls, some of whom have passed out very creditably and are now attached to the hospitals in these provinces, while others are practising as midwives and nurses.

He was elected a Commissioner of the Allahabad Municipality six years ago, and has since been twice re-elected as a member of the Board. He is in charge of the Vaccination Department of the Allahabad Municipality. He is also Honorary Secretary of the "Anglo-Bengali Preparatory School" and Vice-Chairman of the "Indian Girls' School" at Allahabad. Both of these institutions are private ones, and not under Government control.

The Colvin Hospital, the Dufferin Fund, the training class, the vaccination work, the two schools and his extensive private practice among Europeans and Anglo-Indians as well as natives, keeps him well on his legs, making him work from 12 to 14 hours a day.

DR. OHDEKAR is a Past Master of Lodge "Unity" No. 1698 E. C. and also of Lodge "Independence with Philanthropy" No. 391 E. C., as well as 1st Principal of Chapter "Bandeman" and Master of the "Lebanon Lodge of Mark Master Masons".

THE Indian Medical Record.

1st December, 1895.

A SCHEME FOR THE FORMATION OF AN INDEPENDENT COLLEGE OF MEDICINE IN CALCUTTA.

THE scheme published in our Correspondence columns to-day for the formation of an independent College of Physicians and Surgeons in India, gives shape to thoughts and suggestions that have occupied the mind of the local profession for some time past. We have frequently dwelt on the need for action in this direction as the only apparent escape from the present dominating system which closes the doors of all the medical colleges of the country to men outside the official services. This exclusion has been rightly regarded as a hardship, and it is no wonder that men imbued with spirit and enterprise, having a love for their profession, and inspired with ambition to rise and become eminent in its various branches, should seriously consider the unique and anomalous conditions which trammel their calling in this land, and cause them to devise means for ameliorating these conditions in some way or other.

The scheme which we publish to-day has been prepared by a Select Committee, and its general features have been largely discussed by numbers of our brethren outside the Committee, both English and Indian. In giving it publicity, we do so with the assurance that the scheme has, the approval of the leading non-official European and Indian physicians and surgeons of this city. It has been placed before the Council of the Indian Medical Association, and with the sanction of that body, it goes forth to the medical profession of the Indian Empire.

To give effect to the scheme, it is essential that the machinery, and the wherewithal for working it, must be forthcoming. There must be a sufficient number of medical gentlemen, ready willing and able, to form the Faculty of the College, and there must be money sufficient to start and carry on the work. We have no hesitation in stating, that in Calcutta we have enough men, ready, willing and able, to take up the work of the Faculty at once. As to the essential question of the funds needed, we have enough confidence in so grand and noble a cause, to feel assured that it will not lack the support of our brethren nor of the general public in this land. There is in a scheme of this kind all the elements that call for and even ensure every reasonable prospect of success from so inspiring a source as *self-support*. Such a College, inaugurated and established on small beginnings, has all the elements of success in its own conditional working. Provided the men who are "ready and willing and able," who in the first instance, will give their educational services gratuitously; and students and intending graduates who will pay their fees for study and for their examinations, we find a ready source of income. Of course there is the initial expense of furnishing the various classes with diagrammatic illustrations, specimens, apparatus, &c., but these will speedily be forthcoming from already promised funds. Then, again, there is the essential need

of a hospital, dissection, pathological, chemical, physiological and *post mortem* demonstration rooms, where students of the new College should be able to take out their clinical and practical classes. These difficulties may also be overcome by the sympathetic help of the Bengal Government. It ought to be no difficult matter to find a Government, having a declared policy of encouraging private enterprise and of retiring from State-conducted education, willing and ready to look favorably upon a scheme which promises by its fulfilment, to allow the machinery of medical education to be carried on by private enterprise, to the relief of the overburdened exchequer of the State. In general education, all over our large cities in India, we find that the spirit and energy of private enterprise have succeeded in establishing great and flourishing institutions, which are absolutely independent of Government aid or control in their management.

When the scheme for the College has been finally accepted, it will be the duty of the Indian Medical Association to appeal to the Bengal Government and to the Government of India for such encouragement and help as we have briefly indicated for the efficient and successful working of the College. Failing such encouragement from the State, there is still a wide field of promise and hope, for men in real earnest, whose hearts and minds are definitely and solemnly pledged to a righteous and noble cause, cannot be held back by obstacles. All difficulties sink into insignificance where pluck and honest energy are banded in union. And so it will be with this College scheme. It will succeed. Side by side with the huge, well-supported machinery of the famous Calcutta Medical College, the ROYAL COLLEGE OF PHYSICIANS AND SURGEONS OF CALCUTTA may look an impossible dream; a veritable bantling alongside of a gigantic oak. This picture may be only too true, but the early history of the Calcutta Medical College is inspiring in this respect, for it started with the zeal of one *Englishman*, who began his work in a tiled hut and taught his first students the art of surgical dressing and drug compounding, and the treatment of minor ailments in this humble sanctum, which soon found imitators in the form of other zealous *Englishmen* and larger buildings, till after one addition and another, the present College,—the worthy successor of their early and inspiring efforts—stands out as a monument of their toil and of the toil of the many able men, who, following in their footsteps, have given to the Calcutta Medical College its excellent and well-deserved reputation. Have we not also the inspiring example of the Colleges of Physicians and Surgeons of London, Edinburgh and Dublin, and the various Medical Colleges of Europe and America. These all have a record of small beginnings. Nearer home and more to the point have we not the example of the CALCUTTA MEDICAL SCHOOL, established by a band of zealous and earnest men, held together and led on by the hand of the learned and worthy President of Indian Medical Association—Dr. LAL MADHUS MUKERJEE.—This School, though it educates only in the vernacular, was started under great difficulties, but the energy and pluck and zeal of its staff have abundantly proved not only its *raison d'être*, but they have more than justified all their laudable plans and intentions. Two years ago nearly, when Sir WILLIAM ROBERTS—the

well-known Manchester physician and medical member of the Royal Opium Commission—, visited the Calcutta Medical School, we had the pleasure of being present on the occasion, and after this experienced educationalist had carefully inspected the school,—its lecture halls, its chemical, pathological, therapeutical and physiological laboratories, its out-door dispensary, its well-arranged and commodious dissection rooms, and had seen its enthusiastic crowd of hundreds of students, Sir WILLIAM's face beamed with joy and satisfaction, and his words of encouragement and congratulation will not soon be forgotten by the medical staff of the School nor by others who heard them and felt a deep interest and pride in the welfare of this School. Dr. ROBERTS mentioned that he was one of the early promoters of the great and famous Manchester School of Medicine, which now boasts of being a full-blown University, and he said that the success of the Calcutta Medical School was most encouraging and satisfactory, and that its promoters and supporters had every reason to be proud of their success. Very heartily do we wish this excellent medical school a prosperous and expanding career in the future.

What then is to hinder the inauguration and successful career of the "Royal College of Physicians and Surgeons of Calcutta"? NOTHING. With a complete FACULTY drawn from the European and Indian members of our profession in this city, we may safely ask and claim the confidence of our country and of our people, and facing the great work before us with determined, patient persevering energy and toil, look forward to sure and certain SUCCESS.

—:—

THE FIFTH MEETING OF THE COUNCIL OF THE INDIAN MEDICAL ASSOCIATION.

IN compliance with the notices issued, the fifth meeting of the Council of the Indian Medical Association was held in its Library on Friday, 29th November 1895. Present:—Dr. LAL MADHUS MUKERJEE, President, in the chair; Dr. E. W. CHAMBERS, Vice-President; Drs. J. G. ANDERSON, MONEY LALL DUTT, H. W. JONES, Surgeon-Major HODGKINS, and Dr. J. R. WALLACE. After reading the notice calling the meeting with the agenda of business to be brought forward, and after reading and confirming the minutes of last meeting and passing the Association bills, the following items were transacted:—

(1) Read the reply of the Government of Bengal to the letter of the Council of the Association, asking that the President of the Council, Dr. LAL MADHUS MUKERJEE, be accepted as the Council's representative for the privilege of a seat in the Legislative Council of the Government of Bengal. The reply being a promising one, it was resolved that the Secretary should make a similar request to the Government at any future suitable opportunity.

(2) Resolved that the Certificate of membership as now duly engrossed, be signed by the Council as soon as possible and forwarded to members entitled to receive the same.

(3) The list of new members was placed before the Council and they were duly elected.

(4) Read a letter to the Council from Mr. M. J. PHILLIPS, C.M.S., requesting that the Secretary of the Association move in his behalf to have the course of study

and the certificate of C.M.S. as granted to Hospital Assistants recognised by the General Medical Council of Great Britain, in view to this class of practitioners being permitted to appear before the various boards of examiners in Great Britain to obtain British qualifications.

Resolved that the Secretary shall carefully enquire into the matriculation and course of medical study through which Mr. PHILLIP and the class of practitioners to which he belongs have passed, and provided that such matriculation and courses of study be fully equal to the demands of the British Medical Council, the Secretary shall take such action as the case demands. The cost of such proceedings to be borne by Mr. M. J. PHILLIP, C.M.S.

(5). Read a letter from Dr. ROGER G. S. CHEW in which he requests that he might be allowed to represent the Association as its delegate in England, in any representation that the Association might deem fit to make to the Secretary of State for India on the "Medical Reform Question."

Resolved that Dr. CHEW's kind offer be declined with thanks.

(6). Read a letter from Dr. K. G. SIRCAR resigning his seat on the Council owing to protracted ill-health.

Resolved that Dr. SIRCAR's resignation be accepted with the Council's regret.

(7). Resolved, that the Secretary do prepare the First Annual Report of the Association for 1895, and that the 28th December 1895 be fixed for the Second Annual General Meeting of the Indian Medical Association.

(8) THE INDIAN MEDICAL PROVIDENT FUND.—The Secretary reported that the scheme for the formation of the Indian Medical Provident Fund was placed in the hands of Messrs. H. E. ABBOTT & Co., of Calcutta, who have kindly consented to be the Agents of the Fund, while Messrs. S. J. LESLIE & SONS have also consented to be the Solicitors of the Fund. He further reported that nearly 120 persons had expressed their desire to join the Fund. The Secretary also announced that Messrs. H. E. ABBOTT & Co. had expressed a wish that a section of the Fund should be thrown open to Planters and other well-to-do members of the European Anglo-Indian and of Indian Communities. Resolved that the Council approve, the scheme, and of Messrs. H. E. ABBOTT & Co.'s suggestion for the co-operation of the planters and others in the Fund, and that the rules and bye-laws and other provisions of the Fund be prepared and placed before the Council at the earliest opportunity.

(9) THE QUESTION OF MEDICAL REFORM IN INDIA.—The Secretary having placed before the Council the numerous articles from the *Indian Medical Record* dealing with the question of Medical Reform in India, it was resolved that the Secretary do forthwith prepare a clear and exhaustive statement of the whole matter on the lines indicated in the epitomized programme condensed from the *Indian Medical Record* by the *British Medical Journal*, in which the latter organ has given the following brief sketch its complete approval:—

(1) To put a stop to military surgeons going into civil duty; (2) to cause all military surgeons, now in civil work, to return to military duty; (3) to throw the "expert" or specialist's posts and teaching appointments open to competition here and in England; (4) to instal the *Unconvened* as the nucleus of the *Indian Civil Medical Service*,

and to fill up all civil vacancies from the special additions that will be made to this service; and, (5) to utilise military surgeons and military assistant surgeons with British and Indian troops under one centralised organisation, tantamount to an amalgamation of these services.

It was further resolved that the Secretary be empowered to request, and authorise the representatives of the Council of the Association in Bombay, Madras, the N.-W. P. and Oudh, Burmah, the Punjab and the Central Provinces, to co-operate in this movement, and to aid the Association in raising funds for such action as the Council may deem necessary and expedient, either for the support of a delegate to represent the cause of Indian Medical Reform in England, or any suitable representation to Parliament on the subject.

(10). THE FORMATION OF AN INDEPENDENT COLLEGE OF PHYSICIANS AND SURGEONS IN CALCUTTA.—This important matter was very minutely and warmly discussed, and after all the *pros* and *cons* of the case had been fully considered, it was resolved that the scheme as published in the *Indian Medical Record* of 1st December 1895, be placed before the medical profession in India, with a view to early action being taken to inaugurate this scheme.

COMMENTS AND NEWS.

IMPORTANT MEDICAL COUNCIL NOTICES.

(1). EVERY Registered Practitioner should be careful to send to the BRANCH REGISTRAR by whom he was originally registered (*see* the notified addresses) immediate notice of any change in his address, in order that such change may be duly inserted in the "MEDICAL REGISTER"; and also to answer at once any letter of enquiry that may have been sent to him in regard thereto.

(2). It is important for every registered practitioner to remember that if the above request be not complied with, such practitioner is, by Section 14 of the "Medical Act (1858)," LIABLE TO HAVE HIS NAME ERASED FROM THE "MEDICAL REGISTER," and in consequence by Sections 31 to 39 of the said Act, to lose the right to hold certain appointments, to sign valid certificates, or to recover in any Court of Law, charges for professional aid, advice, and visits, and the cost of any medicines, or other medical or surgical appliances, rendered or supplied by him to his patients.

(3). Any medical practitioner, whose name has been removed from the "MEDICAL REGISTER," pursuant to the provisions of the above-cited Section 14 of the Medical Act, should, if he desires to be restored to the "REGISTER," immediately apply to the BRANCH REGISTRAR by whom he was originally registered.

(4). Notice should also be sent to the same BRANCH REGISTRAR of any addition to his qualification that a registered practitioner may wish to have inserted in the "MEDICAL REGISTER."

(5). On April 21, 1883, the GENERAL MEDICAL COUNCIL passed the following Resolution:—

"That the COUNCIL record on its Minutes, for the information of those whom it may concern, that charges of gross misconduct in the employment of unqualified assistants and charges of dishonest collusion with unqualified practitioners in respect of the signing of medical certificates required for the purposes of any law or lawful contract, are, if brought before the COUNCIL, regarded by the COUNCIL as charges of infamous conduct under the Medical Act."

(6). With an earnest desire to put a stop to this wrongful practice, the GENERAL COUNCIL passed the following further Resolution on November 26, 1887:—

"That it be referred to the EXECUTIVE COMMITTEE to consider, under what circumstances a registered Medical Practitioner would render himself liable to the censure of the COUNCIL, in reference to the employment of unqualified assistants."

(7). On 27th February 1888, the EXECUTIVE COMMITTEE, without attempting to make a formal definition of the misconduct in question, reported to the GENERAL COUNCIL that in its opinion, "A registered medical practitioner would render himself liable to the censure of the MEDICAL COUNCIL, in case of the employment of an unqualified assistant in the practice of medicine, surgery, or midwifery on behalf and for the benefit of such registered practitioner, either in complete substitution for his own services, or under circumstances in which due personal supervision and control are not, or cannot be, exercised by the said registered practitioner."

(8). In reference to the procedure known as "covering," the EXECUTIVE COMMITTEE also stated that, in its view, a registered practitioner covers an unregistered person when he does, or assists in doing, or is party to, any act, which enables such unqualified person to practice as if he were duly qualified.

(9). The EXECUTIVE COMMITTEE furthermore called attention to a Resolution, passed by the GENERAL COUNCIL on April 21, 1893, which implies that, in the COUNCIL'S opinion, "any registered practitioner practicing for gain, who knowingly and wilfully deposes a person not registered, or qualified to be registered, under the Medical Act to professionally treat on his behalf, in any matter requiring professional discretion or skill, any sick or injured person, 'should' be subject to the same legal liabilities as a person who falsely represents himself to be a legally qualified medical practitioner; but with special proviso that such enactment 'should' not hinder any duly regulated training of pupils in medical schools or otherwise by legally qualified practitioners, nor the use of trained pupils in partially treating the sick or injured, under the direction, supervision, and responsibility of such practitioners, nor any legitimate employment of nurses, midwives, or dispensers."

(10). From time to time, the COUNCIL has investigated several cases in which registered medical practitioners have been charged with permitting and enabling unqualified persons to practise under cover of the names and qualifications of such registered practitioners; and when the charges have been proved, the COUNCIL had adjudged these practitioners to have been guilty of "infamous conduct in a professional respect," and has ordered their names to be erased from the Medical Register.

MILITARY ASSISTANT SURGEONS WRONGLY DESIGNATED "SUBORDINATES."

It is remarkable that the *Indian Articles of War*, which came into force on the 1st April, should so conclusively uphold our recent contention, that the alteration of the departmental designation of the Military Assistant Surgeons' Service from "Indian Medical Service" to "Indian Subordinate Medical Department," in supercession of the orders of the Secretary of State for India, was not only an illegal step, but an anomalous one, and that therefore, the action of SURGEON-MAJOR-GENERAL RICE was *ultra vires*, and ought not to be permitted to stand. The *Indian Articles of War*, from which we quote, enact:—

"*Clause (8) application of articles* :—These articles shall apply to all

(a) Persons to whom they actually apply at present.

(b) Persons commissioned or gazetted as Native Officers, or gazetted as Warrant Officers of Her Majesty's Indian Forces.

(c) Medical Subordinates *Clause (c) Definitions*. In these articles unless there is something repugnant in the subject or context:—

6. *Medical subordinate* means a Senior Hospital Assistant, a Hospital Assistant of the 1st, 2nd or 3rd class, and a Sub-Hospital Assistant, but does not include an officer.

7. *Superior officer*, when used in relation to a person subject to these articles, includes a Warrant Officer, a Non-Commissioned Officer, and an acting Non-Commissioned Officer."

Now it is absolutely indisputable in the face of this clear ruling, that under the term "superior officer," is included a Warrant Officer, and Military Assistant-Surgeons are all of them Warrant Officers, while some are Commissioned Officers. How then can the term *subordinate* apply to any grade of Military Assistant-Surgeons and much less so to their commissioned grades, and for the same reason how can their service be designated *Subordinate*?

We protest that the interference that was adopted by DR. RICE was a direct violation, not only of the Secretary of State's orders, but the term *Subordinate* as applied to Military Assistant-Surgeons is still in direct antagonism to the *Indian Articles of War*, and the sooner the slur is removed, the better will it be for the reputation of the Office of the Surgeon General with the Government of India.

BILIARY CIRRHOSIS IN CHILDREN.

SEVEN cases presented all the symptoms observed in the adult; but, in addition, in many instances there was hypertrophy of the spleen. So marked is the splenic enlargement where there is not great enlargement of the liver that the true nature of the disease may be easily mistaken. We believe this associated enlargement of the spleen is peculiar to cases of biliary cirrhosis commencing in childhood; a further peculiarity is the frequency with which clubbing of the fingers may be observed; in some instances there was enlargement of the ends of the femur and tibia. The backward and stunted appearance of affected children indicates the influence of the disease on the general nutrition.—GILBERT and FOURNIER, in *Revue des Maladies de l'Enfance*.

DR. NIM CHAND GUPTA.

WE regret to report the death of DR. NIM CHAND GUPTA, first grade Assistant Surgeon, from fever, which took place on Monday last, the 25th November, at his residence at Chasadhopara at the age of 65 years. The deceased gentleman served Government in varied capacities and places in Upper India for a period of thirty years, and was placed in charge of the Calcutta Mayo Hospital before his retirement. The services of DR. NIM CHAND were sought by some of the leading families of Calcutta after his retirement where his professional attainments were highly appreciated. He leaves a large circle of friends and relatives to mourn his loss.

NEW CHOLERA RULES.

A Committee will assemble in Calcutta in January to revise the present Army cholera rules. The Committee will be composed of the Quartermaster-General in India, the Principal Medical Officer with Her Majesty's Forces in India, and the Sanitary Commissioner with the Government of India, associated with MR. TARNER.

THE CONTROVERSY OVER THE HEALTH OF CALCUTTA.

THE Lieutenant Governor of Bengal in his Resolution on the Calcutta Health Officer's Report on the sanitation of this city, makes some controversial remarks on DR. SIMPSON'S views, to which the latter replies in a daily paper as follows:—

"In your leader of to-day on my annual report, you state that SIR CHARLES ELLIOTT, in his Resolution on the Municipal Report, shows conclusively enough that DR. SIMPSON'S allegation that fevers of a typhoid type are largely increasing in Calcutta, is not borne out by figures produced by him. You would be perfectly right, and so would the framer of the Resolution, if the facts as stated were correct, which, unfortunately for the Resolution, they are not. I had intended to let the Resolution pass, for it shows an extraordinary amount of ignorance on the subject of the sanitation of Calcutta, as all these Resolutions issued by unprofessional people on sanitation and on medical matters invariably do. But as you have dealt with the subject publicly and my silence might in this instance seem assent, and thus indirectly retard the works which DR. BALDWIN LATHAM showed were necessary, I may state for your information that I made no such allegation either in my annual report or elsewhere. My contention always has been that the mortality under the heading of fevers and other causes, which are diseases that should be materially reduced by efficient drainage, are on the contrary increasing, and that this is due to the defective condition of the sewers which, in consequence of an obstructed outfall, due to tidal influences and deficient pumping power, are simply elongated cesspools. At the present moment we are living over sewers which are practically never emptied of their sewage for any length of time, and this, apart from the question of leakage, is a condition which is most fatal to the public health. I always make it a point not to ventilate my views in letters in the public prints, but when I see the Government of Bengal so ill-advised as to treat lightly a subject which is of vital importance to the inhabitants, I feel it is time to speak out."

This is as it should be, and we cordially support Dr. SIMPSON.

THAT BRUTAL, CIVIL SURGEON! THE LIE NAILED.

SURGEON-MAJOR J. CROFT, writing from Rajputana, has something to say of the Rev. WILLIAM BONNAR'S article entitled "The English in India" which appeared in the October number of the *Contemporary Review*.—MR. BONNAR tells a story about a Civil Surgeon who extracted two teeth from a native for not removing his face cloth. It is improbable that there are many people in India so credulous as to believe this story even though it reaches them from the pen of a reverend missionary. I am the Civil Surgeon referred to. The tooth extraction story was, of course, a pure invention told of me by a well-known maker of good stories, and may have been repeated by me as I heard the story and in the same spirit—the original story was that I extracted one tooth. That MR. BONNAR should believe a medical officer to be capable of the action he describes, and that he should publish this obvious invention as a fact in one of the leading English magazines is, I think, a sufficient indication of the amount of reliance to be placed upon his statements generally, and of the weight to be attached to his opinions. Of the glowing inaccuracies, misstatements and suppressions, of which MR. BONNAR'S article is mainly composed, I will leave some better qualified person to speak; it should, however, be made known that it is solely owing to the intercession of the very Political Officer be so freely

maligne and bespatters, that MR. BONNAR and his brother missionaries have any footing in the Native States at all. To quote MR. BONNAR with a slight alteration, there is probably not one native ruler in India who would not gladly pay the mission expenses over and over again if thereby he could get rid of its irritating presence.

FEAR IN ANÆSTHESIA BY CHLOROFORM.

SURGEON-MAJOR JOHN SMITH, M.D., I. M. S., General Hospital, Madras, writes to the *British Medical Journal*:—"During my recent holiday in England I attended several of the London hospitals and observed closely the mode of administering chloroform and the results in these institutions. It was over twelve years since I had last witnessed chloroformisation in England, and I had practically forgotten what the process there looked like. What struck me chiefly was the look of terror on the faces of most of the patients as they prepared themselves to submit to the anæsthetic—thus the staring, the struggling, and the shallow breathing, during which I was frequently in terror lest I should indeed witness a death from chloroform. Nothing could form a greater contrast with all this than the happy anticipation of freedom from pain which I may say invariably characterises our patients in the East when chloroform is about to be administered for any purpose. When unconsciousness is setting in, frequently a certain amount of struggling takes place, but it is hardly ever violent, except in the case of the few who, unhappily, have been the victims of drink."

During the ten years I have been attached to the General Hospital, Madras, in which chloroform has been administered about 2,000 times a year, the above has been my invariable experience. During that period not a single death from chloroform occurred. Two deaths occurred during the ten years while the patients were under chloroform—one from hemorrhage, and one from suffocation by stercoraceous vomit.

If DR. LAUDER BRUNTON would turn his attention to this immunity from danger which accompanies the use of chloroform in India, some clue might be obtained towards solving its dangerousness in England. It is a point well worth the exercise of the great abilities of that distinguished therapist."

THE MORALS OF A SURGEON.

The *Hospital* says:—What a man does is the proof to the world of what a man is. Many good people fear that the advance of science will bring about the retrogression of morals and religion. We do not agree with them. But if they cannot accept our judgment, let them weigh well a fact like this: MR. JONATHAN HUTCHINSON, F.R.S., and ex-President of the Royal College of Surgeons, addressed his professional brethren assembled in annual congress the other day, and he thus spoke: "I bore with such equanimity as I could, the discovery that I could not compete with my friend in the ratio of successes obtained (in operations for ovariectomy), and, acting on the rule of conduct that I would never keep a patient in my own hands if I believed that someone else could do what was needed with greater prospect of success, I gave up doing ovariectomies, both in public and in private, and used to transfer my patients from the London to the Samaritan Hospital." Here is a rule of conduct which has never been excelled in moral worth, in any department of professional life or private behaviour. A most far-reaching and truly noble rule is this of MR. JONATHAN HUTCHINSON'S; and the fact that he announced it toward the close of his career in the hearing of hundreds of his

professional brethren, who are almost as familiar as he is himself with the conduct of his professional life, is proof that he spoke mere truth. If these are the morals of men of science, may we not say of men of all professions and callings, *O si sic omnes!*

AN AMERICAN PARABLE OF THE BLACKSMITH AND THE PHYSICIAN.

A CERTAIN man was hanged, and he died, and he left two sons, honest men. Now, one of these sons was a blacksmith; but the other became a physician. And after their father had been taken from them, those brothers made their homes in other lands. And the blacksmith would have prospered, but it befell that some one asked him how his father died. And the blacksmith, looking angrily upon him, answered: "He was hung." For the blacksmith was an honest man. Howbeit presently, when a horse was missing, men gathered and seized and hanged the blacksmith, saying: "This man must take after his father." So the blacksmith did take after his father. And, at the same time, in his own city, one inquired of the physician by what means his father died. And the physician covered his face and wept. But whilst he wept, he considered, saying within himself: "If I say, he was hanged, then shall I shock this man, and give him pain. Nevertheless I must tell the truth." He said, therefore: "My father died of heart failure." And again he wept, the questioner weeping with him. Then this being told, men said: "Doubtless, since his father died of heart failure this good physician and loving son hath made a study of kindred diseases." So they resorted unto him. And the physician became a specialist, and he looked at them who came in and coughed once and sneezed twice, and demanded \$100. And they gave gladly. For the physician was an honest man.

SANITARY VANDALISM.

THE proposal of the Government of India to abolish a considerable number of Deputy Sanitary Commissionerships in order to raise funds for the establishment of a Bacteriological Institute at Agra is one which, if it has really been seriously entertained, is certain to come in for no small amount of severe criticism. Sanitation is still so backward in this country that even a Bacteriological Institute, valuable as it would undoubtedly be, would be too dearly bought at the price proposed. Even as it is, the existing Sanitary staff find it impossible to accomplish more than a tithe of the work which lies at their hands; and in some instances the removal of the Deputy Sanitary Commissioner would mean the practical cessation of detailed sanitary work, and all the good which might be achieved by the Bacteriologists would be counteracted by the evil involved in depriving the country of the already sufficiently meagre protection it may derive from sanitary work.

THE INDIAN MEDICAL PROVIDENT FUND.

THIS Fund is now nearly an established institution. The scheme has received the approval of the Council of the Indian Medical Association, and Messrs. H. E. ABBOTT & Co, the well-known Merchant-Agents, have undertaken the Agency of the Fund. The Bank of Calcutta are to be the Bankers, and Messrs. S. J. LESLIE and SONS the Solicitors of the Fund. As it will afford us much pleasure to see the Fund in an assured and prosperous position, we would urge upon our brethren of every class to send in post-cards to our office, indicating their willingness to join the Fund. The whole prospectus will soon be placed before the profession. The following names have been added to the list of candidates willing to join the Fund:—Asst.-Surgn. W. G. Carleton, I.M.S., Benares; C. B. Buxee, C.M.S., Dhula Junction; K. Krishnamanglu, C.M.S., Shimoga; P. V. Yagambara Moddhar, C.M.S., Jabalpur, C.P.

This makes a total of 113. Let us have a thousand names soon.

THE PROSPECTS OF INDIAN VETERINARY STUDENTS.

A MEMORIAL signed by no less than forty-three of the students of the Bengal Veterinary School at Belgaichia has been addressed to the Lieutenant-Governor, praying for more liberal treatment as regards appointments and emoluments. They point out that the calling of a Veterinary Physician is not held in high repute in this country, and as it has been the traditional occupation of some of the lowest classes of the Hindoo community, it is not likely to have any attraction for young men belonging to the respectable classes of society unless the prospects of the profession are improved and made at least equal to those of the graduates of the Bombay and Lahore Veterinary Colleges.

HARD-WORKED A. M. S. OFFICERS.

The *British Medical Journal* says:—"The conditions of foreign service, especially in India, are exceedingly hard and destructive to health. The medical staff, especially the ill-paid juniors, consider themselves both literally and metaphorically 'sweated' by the Indian Government; they experience all the disadvantages without enjoying any of the advantages which fall to their brethren of the Indian Medical Service." We would strongly recommend a 50 per cent. reduction of the numerical strength of the A. M. S. for India, and their place to be taken by Military Assistant Surgeons.

AN INDIAN L. M. S. IS A UNIVERSITY GRADUATE.

Dr. Frederic G. Hallet, Secretary to the Royal Colleges of Physicians and Surgeons of London, in writing to an Indian correspondent, says:—"A Licentiate in Medicine and Surgery of an Indian University is not a Graduate; the latter term referring, only to Bachelors and Doctors of Medicine." Now Dr. Hallet may be quite right as regards the application of this view in Great Britain, but the laws of this land and the regulations of its Universities give the title L.M.S. dignity of a degree and its holders are graduates.

SHORT ITEMS.

"The jamun is an Indian fruit seldom eaten by Europeans, though not at all unpalatable; if shaken up with a little salt. It is useful in dysentery. The juice of the jamun, made into vinegar by exposing it to the heat of the sun, is used for 'spleen.' By the way, the jamun makes good wine, and even brandy of good quality has been made out of this fruit." So says the *Morning Post of India*.

Marro found that thirty-one per cent. of criminals whom he studied were children of alcoholized parents; and Rossi, out of seventy-one, found thirty-one per cent of the same hereditary taint. This includes those who were criminals from direct intemperance only so far as they were children of drunken heredity.

Mr. W. B. Saunders announces that "An American Year-Book of Medicine," edited by Dr. George M. Gould of Philadelphia, will be ready for delivery on January 1st. It is his intention to publish this work yearly, and he expects it will have an extensive sale throughout the United States, as well as abroad.

All interested in the cause of female education will be glad to hear that Mrs. D. N. Ganguli, B.A., L.B.O.P. and S. (Edin.) has made a highly successful professional visit to Nepal. Her patient was the Rani of the Commander-in-Chief of the Nepalese Army, whom she has treated with most satisfactory results.

Surgn.-Lieut.-Col. and Mrs. Tomes have arrived at Midnapore. Surgn.-Capt. O'Gorman is thus relieved, and goes to Chota Nagpore. He and his sister will be much missed.

Dr. Roger G. S. Odell's connection with the *Indian Medical Record* ceased from the 30th November 1905.

There have been recently three successful cases of excision of the spleen for injury at St. Thomas's Hospital. As these are, we believe, the first successful cases that have occurred in Great Britain, the profession will look forward with interest to learning the details.

A French medical journal says that the authorities at Dieppe have issued instructions to the bathing-police, among which is a paragraph directing them never to seize a drowning woman by the hair, as that might come off, leaving the owner to sink.

The admission of women to the examinations of the Royal College of Physicians of London formed the subject of a petition, which was rejected by a small majority. It is feared the Surgeons will act similarly towards a petition sent them.

At the Esplanade Police Court, Bombay, Drs. DeSilva, Nanji Shamji and Sorabji Rustomji, medical practitioners, were charged with possessing a preparation of opium without a license. The magistrate warned and discharged the first and third accused, and fined the second accused Rs. 10.

The new dissecting rooms in the Calcutta Medical College have already been taken into use. They comprise nine thousand square feet of space and are fitted with marble slabs and all the latest appliances.

We desire to state without any reserve that the letters appearing in this journal on the subject of "Officials and private practice" signed W. C. were not written by Dr. William Coulter of this city.

In the public schools of Germany, the bright pupils are separated from the stupid ones. Medical men do the sorting. Principal Bowford must have undergone some part of his training in Germany.

A monument to Professor Billoth will soon be erected in the court of honor of the University of Vienna. The Council of the Faculty has also decided to erect a monument to Skoda and Rokitsansky.

The *British Medical Journal* stated that at Meer Meer, owing to the boiling of water supplied to the British troops throughout the hot weather, there has been practically no enteric in cantonments during the summer.

The Calcutta Municipality has resolved to continue its subscription of last year to the anti-choleraic experiments inaugurated by Dr. Haffkine.

Alarmed by the ravages of strong drink, the Belgian Government has ordered the display in all school-rooms of a printed placard setting forth the injurious effects of alcohol.

Dr. Gilbert Park is an M.D. of the University of Glasgow. He is a specialist in ophthalmics, and is already acquiring quite a handsome practice in this city.

The *Calcutta Gazette* contains an edict that all graduates of the Calcutta University shall in future wear their academic gowns on all public occasions.

Temperance is the proper control of the appetites; it implies the moderate use of good things, and total abstinence from hurtful things.

Sir Dennis Fitzpatrick opened a hospital, at Nabha, which has been erected by the Raja at a cost of Rs. 80,000.

A new hospital called after the Duchess of Cornwall has been opened at Peshawar by the missionaries there.

Current Medical Literature.

MEDICINE.

The Prevention of Nocturnal Enuresis.

STUMPF offers a rational method, which he has employed with success, for the prevention of nocturnal enuresis. It is based on the fact, that the passage of even a few drops of urine through the sphincter vesicæ excites the action of the detrusor to such an extent that the call to micturate becomes almost imperative. Stumpf's theory is that during sleep the sphincter of the bladder is apt to become relaxed, so that, as the child lies horizontally in bed, a little urine passes the sphincter and enters the urethra. The irritation of this urine causes at once strong reflex action of the detrusor, and the bladder is at once emptied in a full strong stream. It is a well-known fact that in nocturnal enuresis in children the urine does not leak away gradually, but the bladder is emptied at once, a point which is in support of this theory. Stumpf's simple method of preventing this is to allow the child to lie with the pelvis elevated, by means of pillows under the thighs, at an angle of 180 to 185 degrees with the horizontal spine. This elevation causes the accumulation of urine in the bladder to gravitate back and distend the fundus, and thus prevent its pressing upon the sphincter. This method has to be put in action for about three weeks, and by its means Stumpf has succeeded in curing two inveterate cases, one in a boy of nine, and another in a girl of fifteen.

The Etiology of Locomotor Ataxy.

DR. PITRES of Bordeaux, has made extensive investigations in the hope of throwing light upon the still doubtful points in the etiology of this disease. His first results were published in a thesis by Dr. Bereni and comprised 225 cases. The influence of syphilis was found to be great, but not overwhelming, and was by no means in keeping with recent ideas on the subject (*The Lancet*). In considering those cases in which the etiology was certain, there were 125 out of 225—i. e., 55.5 per cent.—and even in many of these cases the syphilis was associated with other causes of tabes dorsalis as hereditary joint affections, alcoholism, sexual excess, etc., so that the exact percentage which could safely be attributed to syphilis was reduced to 22.23 per cent. Of the other patients about 38.44 per cent. had no sign of previous syphilis, and twice during his experience DR. PITRES has seen tabetic symptoms precede syphilitic manifestations, so that these statistics tend to show that though syphilis is a cause it is not by any means the only one, but that many other conditions also play their part in setting up the disease. There is also in DR. BERENI's work a chapter on the investigation of the heredity of tabes, but no direct tendency to inheritance was found.—*N. Y. Med. Rec.*

Objective Signs in Gastric Disease.

LION AND HAYEM, in continuing this subject, make some remarks on the shape of the abdomen under the heading of inspection. (1) Prominence of the abdomen in the upper part is seen in large eaters, such as diabetics. (2) Prominence below may occur in many conditions, as in women who have borne many children, gastroptosis, etc. (3) A central prominence extending from the lower part of the sternum to below the umbilicus, is seen after a full meal in patients with pronounced dilatation without ptosis of the stomach. (4) Flattening of the abdomen with hypogastric prominence occurs in those having dilated stomachs with ptosis. A slight transverse ridge may often be seen corresponding to the lesser curvature of the stomach. The abdomen observed in profile may show: (a) A substernal hollow; this occurs in

inattention, frequent vomiting, etc. (b) An abnormal prominence, mostly subternal or epigastric, due to distension of the stomach. (c) A flattening of the epigastric region with hypogastric prominence seen in gastric dilatation with ptosis.—*B. M. J.*

The Nature and Treatment of Leprosy.

In a paper on leprosy, which was awarded the Alvarenga prize by the College of Physicians of Philadelphia, RIBB concludes:—

1. That leprosy is a specific disease due to the presence of *lepra bacilli*.
2. That leprosy is influenced by race, climate, soil, food, etc., only in so far as these tend to enervation on the one hand or to physical well-being on the other.
3. That experiments have not demonstrated leprosy to be inoculable on man or beast.
4. That leprosy is hereditary.
5. That leprosy is contagious, infectious, and communicable, under conditions not yet understood.
6. That leprosy is both mitigable and curable.
7. That chaulmoogra oil is a drug of unquestionable value in the treatment of leprosy.
8. That leprosy may be completely eradicated from the list of human ills.—*Gaillard's Journal*.

Monoarticular Rheumatism.

HEIDENHAIN calls attention to the occurrence of cases of articular rheumatism with involvement of but a single joint, and an absence of manifestations of an acute febrile disorder. Pain is present usually, but in slight degree. Other causative affections, such as traumatism, gonorrhoea, osteomyelitis, tuberculosis, syphilis, were with certainty excluded and relief was afforded by the administration of full doses of sodium salicylate. In the cases observed the shoulder-joint was most frequently involved; then in the order of frequency the wrist, the elbow, and the ankle. In an additional number of cases two joints were similarly involved. The question is raised whether an insidious endocarditis may not develop in the course of attacks of this kind.—*Medical News*.

The Warm Bath as a Diagnostic Measure.

RICHARDSON calls attention to the use of the warm bath in the diagnosis of diseased conditions of the abdominal cavity. The water of the bath is brought up to the natural temperature of the body, and the patient is allowed to recline in the water with all parts immersed except the face and head for a quarter of an hour before the examination commences. By that time the skin has become flaccid, and the parts beneath, especially the abdomen are more readily felt through the abdominal walls. The method is applicable not only to emaciated subjects, but also to the obese.—*Asclepiad*.

Cysticercus Cellulose in Man.

BERGH publishes the first case observed in Norway. The patient, a healthy young man, had two years and a half previously developed a tumour in the right posterior axillary line, which had become larger and tender for the last four months. At the time of observation it was inflamed and fluctuating, and 7 cm. to 8 cm. in diameter. On incision an elastic bladder, 2 cm. in diameter, was discharged with the pus. On examination by HEIBERG this was found to be the cysticercus of the *tenia solium*.—*Gaillard's Med. Jour.*

Medical Brevities.

Tabes Dorsalis.

If a person has paroxysmal vomiting and complains occasionally of violent rheumatoid pains in the legs, examine most carefully for tabes. You will frequently be surprised

at the ease with which you can make the diagnosis.—*DOCTOR HIRT.*

Convulsions.

Produced by a drug can be produced only in five ways: 1. They may be epileptiform—i.e., cerebral. 2. They may be conceivably due to stimulation of the peripheral ends of the motor nerves. 3. They may be conceivably caused by irritation of peripheral ends of sensory nerves. 4. They may be muscular—i.e., due to a direct action on the muscles. 5. They may be spinal.—WOOD.

Intra-cranial Pressure.

The classical symptoms of intra-cranial pressure are headache, vomiting, and optic neuritis.

—:O:—

SURGERY.

The Treatment of Epistaxis.

MR. SHEILD gives some very instructive remarks upon epistaxis, which will be very useful to most people. He classifies the causes of nose-bleeding as follows:—1. Traumatism, either blows or the result of operation. 2. Ulceration of the mucous membrane, especially small ulcers of the septum. 3. New growths of the nose, especially fibrous polypus and malignant disease. 4. Symptomatic from such diseases as pneumonia, hepatic cirrhosis, cardiac disease, aneurism, fevers, &c. 5. Vicarious menstruation. Before speaking of its treatment, MR. SHEILD gives this useful rule—always look upon epistaxis as a *symptom*, and endeavour to discover its cause. As regards treatment, his remarks may be summed up as follows:—1. If the epistaxis is salutary, leave it alone. Should the bleeding become dangerous and obstinate, proceed thus: Let the patient sit up before an open window—never lie down—so as to keep the head higher than the trunk; use ice locally and to the back of the neck. Immerse the lower extremities in hot water up to the knees, and give small doses of digitalis with ergot every three hours. 3. Speaking of local remedies, the best and only sensible method of using powerful astringents is by first detecting the bleeding spot by proper illumination through a speculum. This done, such remedies as turpentine, sulphate of iron, hazeline, etc., can be applied directly to the spot on an armed probe. 4. Should it be necessary to plug the nares, Cooper Rose's india-rubber tampon should be used, or if this instrument is not obtainable, lint can be used. In either case, always soak the plug in some antiseptic, and cover with boracic acid, and always remove in twenty-four hours. There is a serious objection to the use of the plug, in that it may set up acute middle ear inflammation. 5. Lastly, do not be deceived into mistaking epistaxis for hæmatemesis, as not uncommonly blood from the nose may be swallowed during sleep and vomited afterwards.—*Med. Times*.

Sprains and their Appropriate Treatment.

PRIMROSE holds that the aim of treatment for sprains is the early absorption of effused material and the prevention of adhesions. For this, immediate treatment of a recent sprain, pressure is of paramount importance. This should be applied as follows: The joint—say the ankle, for instance—is placed at a right angle (or, if possible, at less than a right angle) with the leg, then cotton-wool or ordinary cotton batting is applied evenly over the foot from the toes upward to the middle of the leg. The amount of wool must be considerable; loosely applied, and should be fully three inches in depth. Over this is applied the bandage from the toes upward, which is drawn as tight as possible. There is no danger of making too much pressure, provided there is sufficient cotton-wool. This usually alleviates pain

immediately by affording pressure to the blood-vessels and keeping the part at rest. The bandage and wool are removed at the end of a few days, a week at the longest, and carefully instituted passive movement is employed; then the dressing is re-applied to prevent further effusion. In ten to fourteen days cotton-wool may be dispensed with, and the support of an ordinary flannel roller substituted. The patient is able to use the injured joint for ordinary purposes after the lapse of about three weeks in the majority of severe sprains. In sprains of slight severity massage may be begun at once with excellent results, and in old sprains massage is by far the most appropriate treatment and indispensable in order to effect a cure. Heat and cold are at best temporary methods of relieving congestion and do harm if employed too long.—*Canadian Practitioner*.

Color-Blind Women recurring in Two Generations.

WHILE the percentage of color-blindness in men varies from 8 to 5 per cent., in women it is extremely rare, and the proportion is only given as about $\frac{1}{4}$ per cent. WENDELL REBER records the case of the wife of a physician who was color-blind. Two of her sons were stated to be similarly affected, and two of her sisters had the same peculiarity. Inquiry into the family history elicited the fact that all the patient's sisters (numbering three) exhibited impaired color-perception, and that her only brother also possessed the defect. All the members, therefore, of one branch of the family were subjects of sub-normal colour-perception. Their father was one of a similarly afflicted family. Both his brothers and his three sisters were color-blind. Moreover, the father married a woman, who, though possessed of normal color-sense, had an only brother who was entirely color-blind. The history could not be traced back to the patient's paternal grandparents. As far as could be ascertained she thought the grandparents on her mother's side were not color-blind. Two of the patient's three sons were affected, while her daughter was immune. One of the affected sons was twin brother to the one who was free from the defect.—*Quart. Med. Rev.*

Lumbar Puncture for the Removal of Cerebro-Spinal Fluid.

DR. WILLIAM BROWNING states:—

1. The method is simple, easily practiced, and rather attractive.
2. In itself it is usually without danger.
3. By it we certainly can draw off cerebro-spinal fluid.
4. The quantity removed at short sittings has been from one to one and a half ounces in adults.

This, without doubt, represents the amount of free fluid usually present in the lower vertebral canal, even when occluded above.

6. In internal hydrocephalus the relief, if any, is but very temporary. In the common form, due to tubercular meningitis, the result is not worth the trouble, while in the closed or encysted forms it must rather do harm than good.
7. As a diagnostic means, for example in suspected meningeal hemorrhage, it is valuable. As an index of pressure it may also be worth noting.

8. It is worth further trial: (a) as a passing relief in brain tumors not complicated by hydrocephalus; (b) as a substitute for trephining in progressive dementia; (c) in certain spinal troubles; (d) and possibly as a means of applying medication directly to the spinal meninges.

9. In conclusion, it may be said that, while admissible in all cases of brain-pressure, there is as yet no established indication for this procedure except for diagnostic purposes.—*London Med. and Surg. Jour.*

Recovery of Hearing after Twenty-six Years' Deafness.

DR. F. FAULDER WHITE, surgeon to the Coventry Hospital, describes a case of this kind. The patient, aged 85 years, was said to have been deaf from the age of 9 years, and when first seen, heard nothing at either meatus, owing to closure of both Eustachian tubes. Daily politization was instituted, and in one week she heard, at one-half inch, a feebly-ticking watch; in three weeks at three inches; and after three months hearing became normal. The case is recorded as remarkable for the extent of the recovery after so long a period of deafness, and to encourage tentative treatment in apparently confirmed cases of deafness. The mental development has been most marked since hearing has been established. Before treatment she was a good lip reader, and could make use of a limited number of words. Now, after restoration of hearing, she is obliged to learn the alphabet of sound. At first she could not understand many words when spoken slowly. Her education has been greatly neglected.—*British Medical Journal*.

—:O:—

OBSTETRICS AND GYNECOLOGY.

Extra-Uterine Pregnancy at tenth month: Placenta inserted on Intestine.

HOUZEL describes a case in which the patient was last seen on May 1, 1892. A violent attack of hypogastric pain with dysuria set in early in November. On February 10th, spurious labor set in and lasted four days; a decidua appears to have been passed. On March 15th she remained undelivered and still felt pain; there was fever, but no diarrhoea. The sound passed three inches into the empty uterus. The outline of the child could be very distinctly seen through the parietes. On March 18th 1893, abdominal section was performed. The peritoneum was of a singular green tint. The foetus, slightly macerated, lay immediately underneath; its head was deeply engaged in the left iliac fossa, and mouth deformed from pressure. It had developed in the left tube, and the sac had evidently ruptured during the previous November. The placenta had become attached to the small intestines, and was still free from a retrograde change. The foetus was removed, and the cavity which it had occupied was filled with iodoform gauze. On March 28th the placenta began to separate. There was some constitutional disturbance. On April 5th the last piece came away, and convalescence was thenceforth rapid. The drainage tube was removed at the end of April; the orifice of its track closed in a few days.—*Ann. de Gynec. et d'Obstet.*

Pregnancy after Ligation of the Fallopian Tubes.

At the December meeting of the Glasgow Surgical Society, DR. MURDOCH CAMERON and R. M. BUCHANAN, made a report upon the clinical history and *post mortem* examination of a case where pregnancy occurred after ligation of the tubes.

Two years before this conception the woman had been delivered by Cæsarian section of a healthy mature child. DR. CAMERON tied the tubes at that time. Four days after the last Cæsarian section the patient, who was a dwarf and rachitic, died of peritonitis, and the *post mortem* examination was made by DR. BUCHANAN.

The right fallopian tube showed the constricted portion without any trace of lumen, while the left was perverted throughout, although the canal was much narrowed and the plicatures atrophied and irregular.

Dr. CAMERON said that this was the first case in which he had ever found pregnancy to occur after ligation of the tube, and attributed the fact in this instance to his failure to tie the ligature sufficiently tight. He thought it would be especially dangerous to remove the ovaries at such a time, when the veins were enlarged and sepsis might so easily be introduced, and therefore was accustomed to rely upon ligation of the tubes. In his last case of Cæsarian operation he had taken the precaution of putting on a double ligature, cutting between, and making such a separation that he did not think union could possibly take place.

Dr. HECTOR CAMERON said he would not have thought *a priori* that a silk ligature would have permanently obliterated the fallopian tube. There was no analogy between that and an artery. It is fashionable now-a-days, when tying an artery, not to try to sever the inner and middle coats; but he himself always did try to do so, and when that was done, the reparatory process which followed was almost certain to obliterate the artery at that point. There was no analogy to this in the case of the fallopian tube, and it had always struck him that the method which Dr. MURDOCH CAMERON had described in his last case (double ligature and dividing between) was the right one and ought to ensure success.—*Med. & Surg. Rep.*

Induction of Premature Labour.

HUCKLENBROICH publishes a series of 50 obstetric cases of this class. The condition demanding help was in 48 cases pelvic deformity, in 1 uncontrollable vomiting from cancer of the stomach, and in the remaining case advanced morbus cordis. Only 1 patient was lost: in that case there was placenta prævia and transverse presentation. Turning was required, and a tetanic spasm followed. This was complicated by peritonitis and the patient died on the fifth day. Nine children were stillborn, and 20 died before the tenth day, including most where turning was needed. Twenty-one were reared. Labour was not induced in any case before the thirty-fifth week. A bougie as stout as possible was passed into the uterus. The effect was very varied, labour ending from eighteen hours to eight days after the passage of the bougie. Uterine cramp was frequent; opium was used for its relief. In one instance division of the cervix was found necessary.

Wandering Dermoid Tumor.

AT the December meeting of the New York Surgical Society, Dr. WYETH presented a tumor with the following history: "A week ago a Russian woman, 80 years of age, housewife, entered Mt. Sinai Hospital with symptoms of obstruction and of peritonitis supposed to be due to appendicitis, the region of the vermiform appendix being the seat of greatest pain. Her symptoms dated back six days. On opening the abdomen over the appendix, the peritoneum was found to be very thick, with evidences of old peritonitis, but no inflammation or adhesion of the appendix. On passing the finger towards the median line it came in contact with a mass adherent to the omentum half-way between the umbilicus and pubes. On detaching this, it was found to be a dermoid containing yellow hair and other material.

Wandering dermoid seems to be a rare condition. The patient recovered."—*Annals of Surgery and Medicine.*

Post-Partum Hemorrhage.

TRY, first, external stimulation, then bimanual stimulation. Second, Joe internally and externally; throw ether on abdomen: Third, handkerchief soaked in vinegar squeezed dry at fundus of uterus: Fourth, inject hot water, 180°: Fifth, electricity: Finally, tampon uterus with gauze.

It is rarely one is required to go farther than combined internal and external stimulation. The intra-uterine gauze tampon will always stop hemorrhage, but should never be used except as a last resort.—*Canadian Practitioner.*

PHYSIOLOGY. PATHOLOGY AND BACTERIOLOGY.

The Facial Nerve and Lacrymal Secretion.

IN a recent number of the *Deutsche Medizinische Wochenschrift* Dr. FRANKE of Greifswald makes some remarks with reference to the anatomical, physiological, and experimental evidence regarding the nerve controlling lacrymal secretion. KRAUSE's conclusion that the trigeminus has a decided influence on this secretion, and that the facial also takes some part in its control, is alluded to. The evidence for this, lay in the fact observed by KRAUSE that complete extirpation of the Gasserian ganglion did not cause a complete cessation of tears in the eye on the side on which removal had taken place. Dr. FRANKE is inclined to refer this effect, however, to injury to the greater superficial petrosal nerve. The patient whose case Dr. FRANKE describes showed complete paralysis of the left side of the face with only slight secretion of tears on the affected side, although the trigeminus was intact. His view is that the facial nerve is the nerve of the lacrymal gland, and that disappearance of the secretion is determined by a lesion of the facial nerve either involving the geniculate ganglion or an even more central part.—*Lancet.*

"Moral Pathology."

WE are coming to speak of a modern science of ethics as of some new revelation, and such in a sense it is. In the same way we talk of a new planet. Both, in fact, are ages old, but are now for the first time explained to us by a new interpretation. There need be no surprise, therefore, when we find that many suggestions and assertions made in our own day on the authority of original thought and observation have long ago found expression in other phrases, whether these be the maxims of daily practice, the records of independent reflection, or the accepted doctrine of sacred writings. To explain these truths anew in the language of cause and effect is not, therefore, to teach them for the first time, but to corroborate them by establishing their essential connection with other facts of life. Ethical science thus becomes a reconciler of opinions respecting the natural, and what we have known hitherto as the supernatural. Its teaching goes far to verify the real unity of terms apparently so diverse and to show that the laws of action to which they are related, are often, if not always, virtually identical. Recent literature has repeatedly furnished us with suggestions illustrative of this unity. The processes of biology, social usage, and morality, have again and again been proved to follow similar lines of action, and this resemblance is, perhaps, nowhere better seen than in the parallel changes observed in physical disease and moral disorder. We have before us an interesting contribution to this subject in a handbook on "Moral Pathology" by Dr. ARTHUR E. GILES. In a series of brief chapters he traces the progressive effects and variations of moral evil from its probable origin in some act of bodily indulgence—some "fall" of the man, or rather of the child—through further developments to the more or less complete deformation of character. The analogy between moral wrong-doing and disease is carefully and closely followed throughout, and is described with force and clearness. The moral physician, in order to treat successfully the complex forms of soul sickness with which he has to do, must, as is truly said, be

equally well endowed with insight, sympathy, experience, and the influence of personal example. A chapter on moral diatheses will instruct very many. The right use of egotism as a motor of good actions is worth noting, so also is a chapter on the causation of moral disease. We have been particularly attracted to the observations on selfishness; in opposition to this vice we seem to find the clue, to a perfect reformation. DR. GILES's preference for healthy altruism as a remedy rather than for merely negative self-sacrifice, will commend itself to most readers. It is encouraging to find that even in a study so sombre as moral pathology we are in sight of a hopeful prognosis. Moral death, it is maintained, is unknown to man, though a species of soul coma is not. Recovery is always possible, provided that the will captive to evil be aroused to efforts of release by a stimulus of sufficient power. The remarks on treatment, though necessarily short in a work professing descriptive of disease, are characterised in an eminent degree by friendly wisdom and practical good sense. In particular we may notice three: (1) that careful moral training should begin in childhood; (2) that such instruction should at any age, and as far as possible be individual rather than general; and (3) that in order to succeed it must be sympathetic. Such rational suggestions as the above are of happy augury when we regard them as expressing the active purpose of the new and yet primal science of ethics.—*Lancet*.

The Varieties of Phthisis.

DR. A. F. PICQUE proposes a classification of the various forms of pulmonary phthisis according to the modes of onset. He recognises the following thirteen forms: the common form, the pleuritic, the insidious the febrile, the dyspeptic, diarrhetic, chloro-anemic, denutritive (wasting), catarrhal, croupy nervous, dyspnoic and hæmorrhagic (hæmoptoic). The distinguishing characteristics of each form are described but the above enumeration will sufficiently indicate the basis of classification.

A Contribution to our Knowledge of the Parasite of Variola.

VON SICHERER working at the instigation of Professor BUCHNER, the author, like L. PFEIFFER, A. RUPFER, and JACKSON CLARKE before him, has confirmed observations first made by GUARNIERI, who found that in certain animals the cells of the corneal epithelium, which form the boundaries of a vaccination-wound, always contain intracellular parasites, belonging, like those of malaria, to the sporozoa. These parasites are visible by the end of the second day after vaccination. As seen in the drawing of a hæmatoxylin-stained section, magnified 500 diameters, the parasites appear as small, deeply-stained round bodies, which lie for the most part in the protoplasm of the epithelial cells, close to the nuclei. Around each parasite is a narrow clear space. These bodies cannot be mistaken for leucocytes, for they are present before the latter have reached the injured spot. Thin, fresh slices of the vaccinated cornea, when examined on the warm stage, show the parasites as small, bright bodies moving within their host-cells. GUARNIERI has described a form of sporing similar to that observed in the sporozoa of malaria, namely, sub-division into radial segments. The phenomena have been observed in rabbits, calves and pigs. At the end of the second day after vaccination the line of inoculation shows as a grey streak. At the end of the third day ulceration begins, and extends day by day till the whole of the epithelium has been destroyed, and at every stage every epithelial cell which abuts on the ulcerated surface contains a parasite. Similar parasites are present in small-pox. They are not

observed in simple injuries, burns, or croton-oil lesions of the cornea. L. PFEIFFER has found that if the cornea is painted with cocaine solution previous to vaccination, the inoculation is unsuccessful. This observation is of interest in connection with the mode of treatment of variola suggested by PEPPE in America, viz. the internal administration of cocaine. Like the parasites of malaria and other sporozoa, this parasite of variola has been found to be a *normal* parasite; in other words, it will not multiply in artificial media, but only in suitable living cells and tissues. Hence the difficulty of investigating what connection the parasites may have with the causation of the disease. It is to be remembered that KLEIN and MONCKTON COPEMAN have found a bacillus in vaccine lymph and in small-pox crusts, and they think that this fungus may prove to be the direct causal factor in the disease. The question is one of considerable interest, since it has bearings upon the pathology, still unknown, of the common infective fevers. It remains to be seen whether the protozoa of which VON SICHERER is the latest exponent, or the protophyta of KLEIN and MONCKTON COPEMAN, will in the end gain the credit of causing small-pox. At the present day no one doubts that, whatever the cause may be, it is a parasite, either vegetable or animal.

—C—

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

The Disinfection of Rooms after Infectious Diseases.

THE absolute disinfection and sterilization of a room in which a patient with an acute infectious disease has been treated, is considered at present extremely difficult, if not impossible. We refer, of course, to rooms in ordinary houses which cannot be washed down with large amount of strong antiseptic solutions. The usual procedure of burning quantities of sulphur, of washing the walls and removing all movable pieces of furniture, is considered to be all that is practically possible. DR. G. BARNET has been working, in co-operation with DR. TULLAT, for the purpose of determining whether a better method cannot be found for the disinfection of infected rooms, and he claims to have obtained successful results. The substance which he used is a solution of formaldehyde in alcohol. He has devised an apparatus by which the vapours of this substance are diffused through a room, and he says that with it, he can disinfect with absolute certainty, in six hours three hundred cubic metres of air. Culture of various specific micro-organisms placed in the room are rendered absolutely sterile by this process. The vapours of this formaldehyde have no injurious action upon the furniture of the room, and they disappear rapidly after a few hours of airing. The process suggested, and the apparatus devised, appear to us to be rather expensive, but if they do all that DR. BARNET claims, they will prove a very useful addition to our methods of fighting disease.

The Intercommunication of Human and Animal Diseases.

DR. J. W. ALLAN suggests the formation of institutions where the intercommunicable diseases of man and animals could be practically investigated. There can be no doubt as to the importance of such investigation so far as mankind is concerned, for the human species incurs much more risk of danger from the existence of communicable disorders in animals, than do animals from such affections in human beings. However desirable it may be, to have such investigations thoroughly carried out, there are grave obstacles to be

encountered in founding such establishments, the first and most important, being the provision of money. It is almost certain that the Government will not provide it, and it is to be feared that private benevolence cannot be relied upon to achieve this object. So that it is to be apprehended, we must rely upon the establishments we already possess for the investigation of allied subjects, such as the histological and pathological laboratories of the medical and veterinary schools, and special foundations like that of the British Institute of Preventive Medicine to afford opportunities for learning more of these transmissible diseases. There are not many labourers in this field, both in this country and abroad, and it must not be forgotten that the Local Government Board, has for many years past, spent considerable sums of money in the investigation of those disorders of animals which can be conveyed to man. With regard to the suppression of these diseases, it has also to be remembered that medical opinion is, at least as regards some of them—rabies and glanders for instance—ahead of public and legislative opinion.—*British Medical Journal*.

To Practice Deep Breathing.

STAND erect, the feet separated, the right slightly in advance; shoulders and head in natural position; hands lying lightly on the abdomen, the fingers pointing to the umbilicus—compliance with this rule enables the person to use the abdominal as well as the pectoral muscles in respiration. Empty the lungs of air, then close the mouth, inhale slowly through the nostrils, using abdominal as well as chest muscles—the lungs thus receive the utmost possible amount of pure oxygen, and the muscles have exercise. Hold the breath as long as possible, and meanwhile use the ordinary calisthenic exercises—never exercise except the chest is well expanded with air. Exhale slowly, enunciating the bowel sounds as the air passes the lips.—*Annals of Hygiene*.

Late Suppers.

THE old tradition that to eat anything just before going to bed was sure to produce indigestion, and render sleep impossible, is now happily exploded. It is not good, as a matter of fact, to go to bed with the stomach so loaded that the undigested food will render one restless; but something of a light, palatable nature in the stomach is one of the best aids to quietude and rest. The process of digestion goes on in sleep with as much regularity, as when one is taking violent exercise to aid it, and so something in the stomach is a very desirable condition for the night's rest. Some physicians have declared indeed, that a good deal of the prevalent insomnia is the result of an unconscious craving of the stomach for food in persons who have been unduly frightened by the opinion that they must not eat before going to bed, or who have, like many nervous women, been keeping themselves in a state of semi-starvation.

Nothing is more agreeable on retiring for the night than to take a bowl of hot broth, like oatmeal, gruel or clam soup. It is a positive aid to nervous people, and induces peaceful slumbers. This is especially the case of cold winter nights, when the stomach craves warmth as much as any other part of the body. Even a glass of hot milk is grateful to the palate on such occasions, but a light, well cooked gruel is better, and in our climate, during the cold months of winter, should be the retiring food of every woman who feels, as many do, the need of food at night.—*Canada Lancet*.

Shame.

MR. WILLIAM BENJAMIN DAVIES has recently been fined £25 for infringing the Medical Act, by falsely taking and using the title of a surgeon. According to his solicitor, Mr.

DAVIES had gone through the usual medical training up to the final examination, from which he withdrew, so it is quite possible that his medical knowledge was fairly good. But he represented himself as being what he was not, and richly deserved his punishment. His offence is only too common now-a-days in every department of trade. You ask for bread and butter and get presumably bread—though no one has yet defined what bread is—and certainly margarine. It is fair to state that in a recent case the purchaser was told beforehand by the vendor that he would get margarine. Ground coffee is openly sold as a mixture of chicory and coffee. It is useless to say most people like it so—ninety-nine out of a hundred English people do not know what coffee is. In an evening contemporary was recently printed a prize menu for two people to last a week; among other items was a quarter of a pound of coffee price 4d. Conceive the infusion made from four ounces of coffee at 1s. 4d. a pound to last two people a week; but this kind of wash is the average housewife's notion of coffee. A return to the methods of our ancestors—the quack paraded through Cheapside within collar of "jordans" round his neck, the adulterator, whether wholesale or retail, in the pillory at Charing-cross, with his falsely named goods at his feet—would go a long way towards purifying money-getting and preventing robbery. An even more stringent punishment than there is on record, the case being that of a falsifier of wine, who being compelled to drink some of his product, died. Perhaps if this was carried out in every case, the effects would be too uniformly fatal, but the suggestion is one to be borne in mind.—*Lancet*.

—:—:—

THERAPEUTICS AND PHARMACOLOGY.

The Effect of the Local Application of Guaiacol in the Reduction of the Temperature in Typhoid Fever.

MCCORMICK has written a paper on this subject, and, in summing up the article, says he is convinced of the following facts:—

- (1). That guaiacol when locally applied is certain to reduce temperature.
- (2). That with the care that a physician should always use in the administration of drugs, it is absolutely safe.
- (3). That chills will not occur if the temperature is not reduced below 100°F.
- (4). That no deleterious effect is produced upon any of the organs by its use.
- (5). That it is easy to apply, and can be used by any one competent to nurse a typhoid fever case.
- (6). There are no depressing effects following an intelligent use of the drug.
- (7). That by continued use the dose can be gradually lessened.
- (8). That it is far superior to the cold bath; that it can be used by one person; that no appliances are necessary for its use that are not obtainable in every home; that it is much more pleasant to the patient; that it is fully as effective; that patients are not subjected to the danger of moving, and they offer no resistance to its use.

MCCORMICK has thoroughly tried the bath and cold packs, and knows that they have proved very efficacious in many cases, but since his experience with guaiacol has no desire to return to either of them.—*Therapeutic Gazette*.

Walking Backward Cure for Headache.

AN apostle of physical culture says that an excellent and never-failing cure for nervous headache is the simple act of walking backward. Ten minutes is as long as is usually

necessary to promenade. It sometimes, however, requires more than ten minutes to walk at all, if one is very "nervous." But it is not understood that it is necessary to walk a chalkline. Any kind of walking will do, provided it is backward. It is well to get in a long, narrow room, where the windows are high, and walk very slowly, placing first the ball of the foot on the floor, and then the heel. Besides curing the headache, this exercise promotes a graceful carriage. A half hour's walk backward every day will do wonders towards producing a graceful gait.

Ichthyol in Fissures of the Anus.

VAN DER WILLIGEN warmly commends ichthyol in the treatment of fissures of the anus. The pure drug is introduced into the anus by a brush. The contraction of the sphincter forces this into all the folds of the mucous membranes. Little pain is excited. Treatment should be repeated daily. The patient is given liquid diet, and occasionally castor oil. The first patient, who had previously been treated by every means short of operation, was cured in eight days, the other three in two or three weeks. One had already been subjected to operation without benefit. There was no recurrence.—*Therapeutische Gazette*.

Onions in Therapeutics.

DOCTOR STAWSKI experimented for several days upon eight healthy persons in order to determine the effect of onions. About two ounces of the raw vescent were administered each day, along with mixed diet. The result gave no support to the claim that onions promote either diuresis or diaphoresis. In five of the eight cases there was increased body-weight. Appetite, thirst, eructation, peristalsis, and bodily vigor were augmented, the latter however followed by a temporary inclination to somnolence. In general the faeces were made more soft, increased in quantity, and more easily evacuated.—*Medical Standard*.

Correspondence.

AN INDEPENDENT MEDICAL COLLEGE IN CALCUTTA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—As you and many other European and Indian physicians well know, a scheme for the development and establishing of an independent College of Physicians and Surgeons in India has been before us for some time. Such a measure has often been suggested in the columns of the *Indian Medical Record*, and within the past few months, several earnest men have given the matter their best thought and consideration.

The deliberations of these men, who formed themselves into a Special Committee, are worthy of the consideration of the medical profession at large in India, and I therefore, with their permission, beg that the following scheme may be placed before the Council of the Indian Medical Association and set forth and published in the *Indian Medical Record*, in view to its receiving the needful deliberation that it demands from the profession at large, and in Calcutta in particular, before final action is taken.

CALCUTTA, 19th Nov. 1895. Yours, &c., GEO. POGGIE, M.D.

:0:

SCHEDULE FOR THE FORMATION OF THE ROYAL COLLEGE OF PHYSICIANS AND SURGEONS OF CALCUTTA.

OBJECTS.

1. To found and develop a medical college, established and maintained by private effort, and conducted on the lines of the British Schools of Medicine.
2. To establish a Hospital and an Out-door Dispensary in connection with the Medical School, for clinical tuition in all its branches.
3. To provide a liberal and practical medical education, of a high standard, to European, Anglo-Indian, and Indian youths.
4. To grant passports for the practice of medicine to fully trained and qualified persons.
5. To open the way to educational work and hospital appointments for independent physicians in India.
6. By the above or other legitimate means, to encourage self-help and promote original research, and thus advance the status of non-official physicians and surgeons, by affording them the means of special study and scientific advancement.

CONSTITUTION.

1. The College to be designated "THE ROYAL COLLEGE OF PHYSICIANS AND SURGEONS OF CALCUTTA," and to be supported by donations from the general public; also by fees paid by its students and diplomates.
2. The Staff of the College to be formed of Senior and Joint-Professors and of Senior and Junior Demonstrators and Tutors. The Senior and Joint-Professors shall form the Faculty of the College.
3. The College shall be governed by its Faculty who shall elect their own President and Executive Council from among members of the Faculty.
4. The Faculty shall from time to time, frame the Rules and Bye-laws of the College, and administer its affairs generally.

5. The power of granting Diplomas to practice Medicine, Surgery and Midwifery, to persons who have had a complete medical education, and have passed successful examinations, according to the rules of the College, shall be vested in the Faculty.

6. The Diploma to practice Medicine, Surgery and Midwifery, granted by the College shall be styled the "Licentiate of the Royal College of Physicians and Surgeons of Calcutta." It shall also grant a higher Diploma or "Fellowship" under special terms of examination and fees.

7. The preliminary educational test and curriculum of study shall be in strict accordance with the rules laid down by the General Medical Council of Great Britain.

8. *Registration*—Every candidate entering upon the course of study of this College, on production of a certificate of having passed the Preliminary Educational Examination of this College, or a certificate of some other equivalent test, as hereinafter notified, together with a certificate of good character, shall be registered on the rolls of the College as a medical student.

9. The Preliminary Educational Test shall be held quarterly in March, June, September and December, and shall consist of :—

- Physics.
- Arithmetic.
- Algebra.
- Euclid.
- English.
- Latin.
- French, or some Oriental language.

10. The Course of Education of the College shall be for five years and shall embrace the following subjects :—

- (a). Physics, including elementary mechanics of solids and fluids and the rudiments of heat, light and electricity.
- (b). Chemistry, including principles and details which bear on the study of medicine.
- (c). Botany, bearing on Materia Medica.
- (d). Elementary Biology.
- (e). Anatomy, Descriptive and Surgical.
- (f). Physiology and Histology.
- (g). Materia Medica and Pharmacy.
- (h). Pathology.
- (i). Therapeutics.
- (j). Medicine and Clinical Medicine.
- (k). Surgery, including Surgical Anatomy and Operative and Clinical Surgery.
- (l). Obstetrics and Gynaecology, including the Diseases of Children.
- (m). Ophthalmic Medicine and Surgery.
- (n). Forensic Medicine.
- (o). Hygiene and Vaccination.
- (p). Mental Diseases.

11. The Professional Examinations of the College shall be divided into five parts, as follows :—

- First*:—At the end of the first year of study in :—
- Physics.
 - Chemistry (Inorganic).
 - Botany.
 - Practical Pharmacy.
 - General Outlines of Anatomy and Osteology.

Second:—At the end of the second year of study in :—

- Chemistry (Organic).
- Practical Chemistry.
- Physiology and Histology.
- Anatomy (complete).
- Materia Medica and Pharmacology.

Third:—At the end of the third year of study in :—

- Materia Medica and Therapeutics.
- Pathology.
- Hygiene.
- Medicine.
- Surgery.

Fourth:—At the end of the fourth year of study in :—

- Ophthalmic Medicine and Surgery.
- Pathology.
- Jurisprudence.
- Obstetrics and Gynaecology.
- Medicine.
- Surgery.

Fifth or final for the Diploma in :—

1. Medicine (clinical).
2. Surgery (clinical and operative).
3. Obstetrics and Gynaecology (Clinical and Operative).
4. Therapeutics.
5. Mental Diseases.
6. Public Health and Vaccination.

Special Examinations for the Diploma of the College for senior students, undergraduates and others who have completed their studies in other medical schools and colleges, will be held quarterly in March, June, September and December.

Students of this College who have failed at the regular yearly examination of the College will be permitted to appear at special quarterly examinations in such subjects as they have been reverted for a fixed period.

12. *Exemption from Preliminary and Junior Professional Examinations.*

(a) A candidate presenting a certificate of having passed the Entrance Examination of any Indian University, or other recognized equivalent test—as accepted by the General Medical Council of Great Britain—or of the High or Middle School Examinations of India, shall be exempted from passing the Preliminary Examination of this College.

(b). All persons holding British or Foreign Diplomas to practice Medicine, may obtain the Diploma of this College by passing the Final Examination and paying the fees for the said examination and for Registration of Diploma.

(c). All graduates of Indian Universities may obtain the Diploma of this College under the terms of para. (b).

(d). All undergraduates of recognised universities who have attended a complete five years' course of medical study, may be admitted to the last two examinations on payment of the special fees thereof and for registration.

(e). All Military Assistant Surgeons holding Certificates or Diplomas from the Medical Colleges of Calcutta, Madras, and Bombay, who have had five years' medical practice in British Military Hospitals, will be admitted to the Final Examination on the above terms.

(f). All Hospital Assistants holding the Certificates of Indian Medical Schools, who have ten years' service, and who shall pass the Preliminary Examination of this Col-

lege, shall be admitted to the last two examinations, on payment of fees for the same, and for Registration of Diploma.

(g) Medical Students of Indian Universities and Schools are eligible to appear at the examinations for the Diploma of this College, on production of evidence of having attended the necessary courses of instruction of any recognised Indian School with a complete curriculum.

13. *The fees of the College* shall be as follows :—

| | |
|------------------------------------------------|------------|
| Preliminary examination | ... Rs. 15 |
| Tuition (per annum in advance) | „ 60 |
| Examination (for each) | ... „ 10 |
| Final Examination for Diploma and Registration | ... „ 50 |

Regular students of this College, who do not complete their course of study, and who desire to continue their studies or to qualify elsewhere, may receive Certificates of attendance at lectures and other courses on payment of fifty rupees for each course. In calculating the amount due for these Certificates, the payments made for tuition in the College will be deducted.

14. *The Special Fees* for students, undergraduates, graduates, and diplomates of other schools, or other persons who, by the rules of the College shall be considered eligible for the examinations for the Diploma of this College, shall be as follows:—

| | |
|-------------------------------------------------------------|------------|
| Entrance Fee | ... Rs. 25 |
| Junior Professional Examinations including 1st, 2nd and 3rd | ... 50 |
| Senior or 4th Examination | ... 100 |
| Final Examination and for Registration of Diploma | ... 150 |

THE MALARIAL PARASITE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you or any of your readers kindly inform us, through your esteemed journal, the results of the experiments performed at Hyderabad by Dr. LAWRIE and others on malaria, which appeared in some "lay papers," and was in no part given publicity to in the *Record*. These experiments, "the papers say," led Dr. LAWRIE to demonstrate that the micro-organisms, discovered by LAVERAN and other Italian observers, attributed to be the cause of malaria, were not real micro-organisms, but mere nuclei of white blood cells, altered by the degenerative effects of the disease; and that the supposed presence of the so-called "germs of malaria" under the microscope being no other than the colored nuclei resulting from the staining imparted to that part of the cell. This seems to be a new departure from the present path of the etiology and pathology of the disease. I would earnestly enquire what the "malaria-parasite party" has to say on this, and how, and in what light, do the eagle-headed Americans and professors at home look at this discovery. I do not for a moment doubt that there are many who support the parasitic theory of the disease, yet there may be some who also criticise it. Anyhow, anything that comes from such a man as Dr. LAWRIE, who is already reputed to be an earnest seeker after truth, must have its due consideration.

Yours &c., R. YELLISH NIDU, G.H.M.S.

ELLICHPUR, 16th November 1895.

(We have not yet seen the account of Dr. Edward Lawrie's researches in lay professional paper, and what has appeared in the lay press cannot be accepted as authentic, for, it does not bear the stamp of the author's sanction for its publication. Comments on such reports as have found their way into the lay press, are seen in some of the English medical papers, but obviously these comments are of no weight since Dr. Lawrie has not yet declared his views.)—ED., J. M. R.

REVIEWS.

THE DISEASES OF CHILDREN'S TEETH: their prevention and treatment. A manual for medical practitioners and students. By R. DENISON PEDLEY MITK, L.D.S., Eng., F.R.C.S., Edin., Dental Surgeon to the Evelina Hospital for Sick Children, Southwark, London, 8vo., pp. 268, clearly indexed and copiously illustrated. (Publishers: J. P. SAGE, London, and S. S. WHITE, Dental Manufacturing Co., Philadelphia, Pa, 1895.)

Pleading for the supplementary of theory with a practical course in dentistry, and urging upon the general medical practitioner the necessity for acquiring an accurate knowledge of dental disorders, which may be reflex as the result of some departure from the normal performance of the functions of nutrition, or direct as the result of decay and give rise to reflex lesions of a grave character in many localities where there are hundreds of children but no dentist. Dividing his subject into eight sections, to each of which he exclusively devotes one chapter, the author first describes the structure of the teeth and then carrying us on through the eruptive stages shows us how caries springs up, but may be prevented or its ill effects removed. He calls particular attention to the careful hygiene of the mouth, and showing how absolutely dependant the general medical practitioner, and the dentist are on each other for mutual support, and successful results, points out that in many instances an aching tooth may be relieved by abdominal medication, while many reflex diseases that threaten the patient's life may be effectually treated only by lancing the gum, or removing the tooth or decay, that acting as a foreign substance is doing all the damage, as all the medicine in creation would be useless in these latter cases. He believes in palliative treatment, but at the same time inveighs seriously against drugs containing salts of mercury. Next taking us over the internal structure of the tooth and showing its intimate connection with the nervous, arterial, venous and osseous systems of the entire animal economy, treats of the various diseases to which *Dens* is heir, and how they may be averted or cured, and then when all other means have failed or are impracticable, he teaches in eloquent language *how* to "fill" hollows, remove teeth and their stumps and take "impressions" of the mouth, so that art may furnish what nature has decided to destroy.

He cites a copious bibliography of renowned authors, and to fully explain how diagnoses may be made, shows the mutual dependance of the medical man and dentist on each other, embodies in their proper places extracts from his case book of the symptoms presented, the diagnosis arrived at, and the treatment adopted in a large number of instances.

THE METHODICAL EXAMINATION OF THE EYE, being Part I of a guide to the practice of Ophthalmology for students and practitioners. By WILLIAM LONG, F.R.C.S., Eng., Surgeon to the Royal London Ophthalmic Hospital, Moorfields, and Surgeon to, and Lecturer on Ophthalmology at the Middlesex Hospital. Crown 8vo., 98 pp., illustrated with numerous wood-cuts. (Publishers, LONGMANS GREEN and Co. London and New York, 1895.)

Part II has not yet reached us; but if it be anything like part I, it will be a book really worth having in the

Surgeon's library. In 96 pages of clear bold type the author devises a routine method by which the student may study the affections of the eye and learn to so accurately examine each case as to render erroneous diagnosis or unwarranted operations an utter impossibility. Dividing the examination of the eye into three stages: (1) external, (2) the visual, and (3) the ophthalmoscopic. Mr. Long carefully guides the student or reader from the *alpha* of anatomical structure to the *omega* decision as to what really ails the eye of the patients; but does it in so concise and compact a manner that while he does not crowd the student with too much to remember nor terrify him, as some authors do by laborious, lengthy and soporific detail of description, he succeeds in teaching in few words *everything* that the eye-student requires to be taught and furnishes him with a *handy* book of reference when memory flags, or he may be in doubt as to what he should do.

The work is thoroughly up-to-date, and the illustrations, which the author tells us were drawn from photographs taken by Mr. D. MARSHALL, the curator at Moorfields, are extremely well chosen to explain the various details of "Manipulation" on which depends at least half of the ophthalmic Surgeon's skill and professional reputation in the treatment of the eye, which is the most delicate organ in the whole body, and requires very tender handling, lest a trifle of undue pressure or the most trivial carelessness may send a patient blind for the remainder of his or her lifetime.

Government Medical Gazettes.

GOVERNMENT OF INDIA.*

The following promotions are made, subject to Her Majesty's approval:—

To be Surgn.-Capt.—P. B. Haig, L. W. A. Fullerton, R. H. Maddox, E. V. Hago, M.D., H. G. Melville, A. O. Hubbard, C. G. B. Scott, H. A. Smith, D. R. Green, G. McI. O. Smith, H. M. Earle, J. G. Hulbert, P. C. Gabbett, J. L. Macre, T. E. Swinton, S. H. Burnett and T. Jackson from 27th July 1895.

To be Hony. Surgn.-Capt.—S. E. Carraplett, from 30th Augt. 1895.

To be Hony. Surgn.-Lieut.—T. Baptist from 23rd Augt. 1895; H. Tallent from 30th Augt. 1895.

The Queen has approved of the retirement of the under-mentioned officers:—

Bde.-Surgn.-Lieut.-Col. A. Barry, M.D., from 31st Augt. 1895.

Hony.-Surgn.-Capt. J. Hamilton from, 15th June 1895, and G. A. Hottinger from 8th July 1895.

Extraordinary leave for 12 months without allowance, is granted to Civil Asst. Surgn. R. Bryson from 21st Jan'y. 1895.

The charge for inserting a Domestic Occurrence is Re. 1 for subscribers and Re. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

WEIR.—November 6, Fatehgarh, the wife of Surgeon-Major R. R. Weir, I. M. S., of a son.

McNAUGHT.—November 5th, at Deolali, the wife of Surgeon Captain J. G. McNaught, M.D., Army Medical Staff, of a daughter (still born).

BOLSTER.—At Subathn, on the 14th November, 1895, the wife of Surgeon-Major Bolster, A. M. S., of a son.

MARRIAGES.

BUIST-SPARKS—WHITLEY.—At St. Paul's Cathedral, Ranchi, on the 6th November, by the father of the bride, assisted by the Rev. F. C. Boyd, Arthur Buist-Sparks, Surgeon-Captain, Indian Medical Service, to Florence May Whitley, youngest daughter of the Right Rev. the Bishop of Chota Nagpur. Scotch and English papers please copy.

MAWHINNY—PARKIN.—Oct. 28th, at the Church of the Holy Trinity, Murree, Punjab, Surgeon-Captain R. T. W. Mawhinny, A. M. S., to Elizabeth Parkin Dell, Murree.

DEATH.

KIRK.—On the 3rd November, at Stratford, Elizabeth, widow of Rupert Kirk, Surgeon, 2nd Light Cavalry, Rajkote, India, aged 89.

NOTICES TO CORRESPONDENTS.

HINTS TO CONTRIBUTORS.

1. Write plainly and briefly and to the point. 2. Write on one side of the paper only. 3. Save postage by sending your papers by "Book Post," the wrapper having its sides open. 4. Every member of the Profession in India should do his little share in adding to the general stock of knowledge.

*Corrected up to and for the 18th November 1895.

†Corrected up to and for the 23rd November 1895.

of tropical disease. 5. Write up interesting cases or a series of cases, give statistics bearing on the history, causation, prevention and treatment of disease. 6. Bear in mind that this Journal is a channel of communication between the members of our profession in the East; therefore send "Personal and General News items," and they will be recorded. 7. Write your views on socio-political topics, connected with the profession, official and non-official, in order to advance the interests of all sections of our calling. 8. Newspapers and journals sent for notice should have the parts intended for observation marked.

G. W. B. and others.—The Association Certificates will issue shortly. They are now being signed by the Council.

R. B.—The College of Physicians of London gets the *Record* and Dr. Hallet will see our note on the mistake he has made.

W. A. W. (Jalpaigori).—The matter is still under consideration and we sincerely hope it will soon be settled.

Undelivered Copies.—Kindly read our "Business Notices." If a post-card notifying delay in receiving the *Record* is not sent us in time, we can take no action thereon, owing to postal rules.

A. H. L. (Vizianagram).—Please fill up the application form to be found in the I. M. Association's advertisement in the *Record* in your own handwriting, and we shall be glad to have you proposed and elected.

W. C. McM.—Make a strenuous effort to get British qualifications.

Assistant Surgeon (Oudh).—The representation is being considered.

E. D. B. (Lucknow) writes to say he has a specific for leprosy, and would like it tried by those interested in the subject. We would advise his sending a supply of the "specific" to Dr. Carleton, Superintendent of the Leper Asylum at Subathu.

C. A. N. (1)—For the requirements of the M. R. C. S. Eng., see the *Medical Register and Directory of the India Empire*, to be had from this office. (2) A graduate of an Indian University can claim exemption from the junior professional examination of the M. R. C. S. diploma, by virtue of his L. M. S. or M. B. from India. (3) An Indian graduate ought to pass any British examination and be back in India within six months at the most. He might do it in four months easily. Rs. 4,000 to 5,000 ought to cover all expenses. (4) Electrical therapeutics can be studied in any British school.

ACKNOWLEDGMENTS.

We have much pleasure in acknowledging the following Literary Contributions and Letters from:—Brig.-Surgn. Lieut.-Col. Kenneth Macleod, M.A., M.D., LL.D., F.R.C.S. England; S. J. Mullens, C.M.S., Srivilliputur; Rai Bahadur Meher Chud L.M.S., Amritsar; R. P. Banerji, B.A., G.B.M.S.L., Rajputana; Brig.-Surgn. Lieut.-Col. G. Kidg. M.B., LL.D., F.R.S., C.I.E., Calcutta; Surgn.-Capt. Patrick Hehlr, M.D., F.R.S.E., F.R.C.M.S., D.P.H., Hyderabad; Edward Balm, C.M.S., Hyderabad; Michael Tindale, C.M.S., Chinnab; K. K. Velu, C.M.S., Calicut; Z. Feldstein, M.D., Calcutta; Geo. Pogose, M.D., Calcutta; Yelliah Nidu, G.B.M.S., Ellichpur; and others.

APOPLEXY.

APOPLEXY occurring in early adult life is much more frequently due to syphilis than embolism, and syphilis is a factor in a third of all apoplexies, at least in large cities. Apoplexies are increasing in disproportionate frequency. The disease does not especially affect brain workers if they live temperately, but rather spares them. An attack is sometimes a conservative agent, calling a halt to excessive activity and intemperate living, and actually prolonging life. About one-fourth of those stricken with apoplexy die from the attack (hemorrhages being the most dangerous, thromboses, especially syphilitic, being least so). The average duration of life of those who have and survive one shock is over five years. The chances of a second attack before the fourth year are always considerable, yet do not amount to fifty per cent. and are inconsiderable so far as hemorrhages are concerned. Thromboses are much more apt to recur than hemorrhages.—DANA in *N. Y. Med. Rec.*

TREATMENT OF GONORRHOEA.

THE results reached in the treatment of these cases seem to warrant, according to DR. CHRISTIAN, of Philadelphia, the following conclusions: 1. That irrigation is a distinct advance in the treatment of gonorrhoea; in fact, up to a certain point it must be considered the proper treatment for that disease. It relieves *ardor urinae* and chills more promptly than any other form of treatment. It is attended with a much smaller proportion of complications such as total urethritis and epididymitis. 2. That permanganate of potassium is the best remedy for the purpose of urethral irrigation. 3. That irrigation alone cannot be relied upon to absolutely cure specific urethritis. For the cure of the thin mucopurulent discharge which appears at the meatus in the morning, some astringent injection used by the patient himself is necessary. 4. That simple non-infectious urethritis can be cured in from ten to twelve days by daily irrigations with permanganate of potassium. The writer is of the opinion that, where it is possible to carry out irrigation of the urethra with permanganate of potassium solution twice daily, this procedure very materially lessens the duration of the disease. The solutions used were as follows: bichloride of mercury, 1 to 15,000, increasing the second week to 1 to 8,000; nitrate of silver, 1 to 6,000, increasing to 1 to 3,000; permanganate of potassium, 1 to 4,000, increasing to 1 to 2,000; trikresol, one-half to one per cent.—*Therapeutic Gazette*.

TRANSPPOSITION OF VISCERA.

Dr. H. J. Herrick reports a case of *transposition of the viscera* in a German labourer set 25, at present in the Lakeside Hospital. His spleen could not be made out, and his stomach appears to have changed place with his liver, which latter was in perfect position and normal, except that it was on the left side. His heart is normal in size and correctly placed, save that it is on the right side, and the apex-beat is in the fifth intercostal space, and about an inch from the nipple toward the median line.

GREEN ASCITIC FLUID.

An Italian, presenting every one of the symptoms of *ascites*, consulted Dr. Marcello Hartwig, who forthwith tapped him removing over five quarts of an intensely green liquid containing large quantities of bile, bilirubin, fatty round cells, and a few eggs belonging to either *ascaris* or *tenia*. A second tapping was made five weeks afterward and proper drainage applied. The progress of the patient and the history during recovery established the fact that he was suffering from an *echinococcus cyst stimulating ascites* and communicating with a bile duct in the liver.
